**Experimental**

**Synthesis of self-standing hollow NiCo$_2$S$_4$ single crystalline nanorod arrays on FTO glass substrates.** The details were described as follows: FTO glass substrates were first sonicated in acetone and ethanol, and then dried by compressed air. Then, FTO glass substrate are suspended in 30 mL aqueous solution containing CoCl$_2$·6H$_2$O, NiCl$_2$·6H$_2$O and urea (35 mM). The total concentration of Co$^{2+}$ and Ni$^{2+}$ cations is 15 mM. After above aqueous solution are subsequently placed at 95 °C for 12 h to form metallic carbonate hydroxide precursors on FTO glass substrate, and rinsed by DI water and ethanol. The products are thermally decomposed under air atmosphere at 400 °C for 1 h with a heating rate of 5 °C min$^{-1}$, forming metal oxides...
nanostructure. When the metallic carbonate hydroxide precursors are reacted with H$_2$S gas for 12 h at room temperature, and then are thermally decomposed under Ar atmosphere at 400 °C for 1 h with a heating rate of 5 °C min$^{-1}$, forming metal oxides-metal sulfides core-shell nanostructure. Finally, after the acid etching process to remove metal oxides, metal oxides-metal sulfide core-shell nanostructure was transformed into hollow metal sulfide nanostructure.

**General Materials Characterization.** The product morphologies were directly examined by scanning electron microscopy (SEM) using JEOL JSM-6700F at an accelerating voltage of 5 kV. Transmission electron microscopy (TEM) observations were carried out on a JEOL 2010 microscope operating both at 200 kV. X-ray diffraction (XRD) was performed on a Philips PW-1830 X-ray diffractometer with Cu Kα irradiation (λ=1.5406 Å). The step size and scan rate are set as 0.05° and 0.025°/s, respectively. X-ray photoelectron spectroscopy (XPS) was measured on a Perkin-Elmer model PHI 5600 XPS system with a resolution of 0.3-0.5 eV from a monochromated aluminium anode X-ray source with Kα radiation (1486.6 eV).

**Characterization of Quantum Dot solar cells (QDSCs).** QDSCs were made by sandwiching the as-prepared CEs and the photoanodes using Surlyn films (25μm) as the spacer. The aqueous polysulfide electrolyte is the aqueous solution of 2 M Na$_2$S and 2 M S. The thermally platinized FTO glass prepared by pyrolysis of H$_2$PtCl$_6$ was used as the reference CE. ZnS modified CdSe quantum dot sensitized TiO$_2$ film was used as the photoanode, prepared by the so-called successive ionic layer adsorption and reaction (SILAR) method. The TiO$_2$ electrodes are composed of 100 nm dense
layer made by the spray pyrolysis of titanium diisopropoxide bis(acetylacetonate), 10 μm transparent layer made of 20 nm anatase nanoparticles, and 4 μm light scattering layer made of 400 nm TiO₂ nanoparticles. For the growth of CdSe on the TiO₂ electrode, the TiO₂ electrodes were successively immersed in two different solutions for 1 min each inside a glovebox under N₂ atmosphere: one consisting of 30 mM Cd(NO₃)₂ dissolved in ethanol, another of 30 mM Se²⁻ in ethanol prepared by the Grätzel’s method.² Following each immersion, rinsing and drying was carried out using ethanol and N₂ gas, respectively. The processes were repeated 8 times. Then, the CdSe sensitized TiO₂ films have been coated with ZnS layer, by twice dipping alternately into 100 mM Zn(CH₃COO)₂ and 100 mM Na₂S solutions for 1 min/dip, rinsing with the ultrapure water between dips.

The photocurrent-voltage (J-V) characteristics of QDSCs were measured using a Newport AM 1.5G solar simulator (model 91192) at the light intensity of 100 mW cm⁻², calibrated by a standard silicon reference cell. The active area of QDSCs was set at 0.16 cm², determined by a square mask. Incident photo-to current conversion efficiency (IPCE) was measured on the basis of a Newport Apex Monochromator illuminator (model 70104). The incident photon-to-current conversion efficiency (IPCE) was measured on the basis of a Newport Apex Monochromator illuminator (model 70104). Electrochemical measurements were carried out on a CHI 660D. For electrochemical impedance spectroscopy (EIS) measurement, the symmetrical cells based on identical CEs (under dark) were carried out at zero V with the AC amplitude
of 10 mV and the testing frequency range was set from 1000 kHz to 100 mHz. The scan rate was set at 5 mV s\(^{-1}\) in the Tafel polarization measurement.
Figure SI-1. XRD patterns of the products formed after Step I (A), II (B), III (C), and IV (D) of scheme 1.
Figure SI-2. EDX spectrum of hollow NiCo$_2$S$_4$ single crystalline nanorod. Cu element is raised from the Cu mesh, and C element comes from carbon film on Cu mesh.
Figure SI-3. (A) TEM image and (B, C) EDX results of the NiCo$_2$S$_4$ nanorods transferred from the (Ni, Co)(CO$_3$)$_{0.5}$OH nanorod under H$_2$S atmosphere for more than 4 days. Cu and C elements come from Cu grid and carbon film on Cu grid. Co, Ni and S elements should be ascribed to NiCo$_2$S$_4$. No O element is detected from EDX spectrum, indicating that the (Ni, Co)(CO$_3$)$_{0.5}$OH nanorod is fully reacted with H$_2$S to form NiCo$_2$S$_4$.
