Materials and reagents.

5,6-Dioctyloxy-naphtho[2,1-b:3,4-b']dithiophene (1) and 5,6-dioctyloxy-2-tri-n-butylstannyl-naphtho-[2,1-b:3,4-b']dithiophene were synthesized according to reported method. Organic solvents used in this work were purified using standard process. Other chemicals and reagents were used as received from commercial sources without further purification. Transparent conductive glass (F-doped SnO$_2$, FTO, 15 $\Omega$, transmittance of 80%, Nippon Sheet Glass Co., Japan) was used as the substrate for the fabrication of TiO$_2$ thin film electrode.

**Characterizations.**

UV-vis absorption spectra of dye solutions were recorded with a Shimadzu Model 3100 UV-vis spectrophotometer. Cyclic voltammetry (CV) measurements were performed with an Autolab analyzer using a typical three-electrode electrochemical cell in a solution of tetrabutylammonium hexafluorophosphate (0.1M) in acetonitrile at room temperature under argon. The scan rate was 50 mV/ s. Dye adsorbed TiO$_2$ on conductive glass was used as the working electrode, a Pt wire was used as counter electrode, and an Ag/Ag$^+$ electrode as reference electrode. The potential of the reference electrode was calibrated by ferrocene, and all potentials mentioned in this work are against normal hydrogen electrode (NHE). The film thickness was measured by a surface profiler (VeecoDektak150, USA). The geometrical and
electronic properties of the resulted sensitizers are calculated by density functional methods using the Gaussian 03 program package at the B3LYP/6-31G(d) level.

**DSSC Fabrication and Photovoltaic Measurements.**

TiO$_2$ films (12 µm) composed of 6 µm nanoparticle (20 nm) layer in direct contact with the FTO substrate and 6 µm light scattering particle (80% 20 nm TiO$_2$ + 20% 100 nm TiO$_2$) layer were fabricated with a screen printing method and used in this study. The films were sintered at 500 °C for 1 hour to achieve good necking of neighboring TiO$_2$ particles. The sintered films were then treated with 0.05 M TiCl$_4$ aqueous solution at 70 °C for 30 min followed by calcinations at 450 °C for 30 min. When TiO$_2$ electrodes were cooled down at 120 °C, the electrodes were dipped in dye solutions (0.3 mM dye + 10 mM DCA) for 16 hours at room temperature. The Pt-coated FTO as a counter electrode and the dye-loaded film were separated by a hot-melt Surlyn film (30 µm) and sealed together by pressing them under heat. The liquid electrolyte was a solution of 0.05 M I$_2$, 0.1 M LiI, 0.6 M 1,2-dimethyl-3-propylimidazolium iodide (DMPImI) and 0.5 M 4-tert-butylypyridine (TBP) in acetonitrile. The quasi-solid-state gel electrolyte was prepared by mixing 5 wt% poly(vinylidenefluoride-co-hexafluoropropylene) with a redox solution containing 0.05 M I$_2$, 0.1 M LiI, 0.5 M TBP and 0.6 M DMPImI in 3-methoxypropionitrile under heating at 100 °C until all solids were dissolved. After introducing the electrolyte or the hot gel solution into the internal space of the cell from the two holes predrilled on the back of the counter electrode, the holes were sealed with a Surlyn film covered with a thin glass slide under heat. The
working performance of the DSSC was tested by recording the current density-voltage (J-V) curves with a Keithley 2400 source meter (Oriel) under illumination of simulated AM1.5G solar light coming from a solar simulator (Oriel-94043A equipped with a Xe lamp and an AM1.5G filter). The light intensity was calibrated using a standard Si solar cell (Newport 91150). A black mask with aperture area of 0.2304 cm$^2$ was used during measurement to avoid stray light. The electron lifetimes were measured with intensity modulated photovoltage spectroscopy (IMVS),$^{[S2]}$ whereas electron densities at open-circuit were measured using charge extraction technique.$^{[S3]}$ IMVS analysis and charge extraction were carried out on an electrochemical workstation (Zahner XPOT, Germany), which includes a white light emitting diode and corresponding control system. The intensity-modulated spectra were measured at room temperature with light intensity ranging from 20 to 120 W m$^{-2}$, in modulation frequency ranging from 0.1 Hz to 10 kHz, and with modulation amplitude less than 5% of the light intensity. Three identical devices were tested in each case with standard deviation less than 5%. Action spectra of the incident monochromatic photon-to-electron conversion efficiency (IPCE) for the solar cells were obtained with an Oriel-74125 system (Oriel Instruments). The intensity of monochromatic light was measured with a Si detector (Oriel-71640).
