Experimental procedures and data

**General Methods.** The corresponding starting materials were synthetized using oven-dried glassware under a nitrogen atmosphere containing a teflon-coated stirrer bar and dry septum. All halogenation reactions were performed at ambient O$_2$ pressure in oven-dried 20 mL vessel containing a teflon-coated stirrer bar and dry septum. All reactions were monitored by GC using n-hexadecane as an internal standard. Response factors of the products with regard to n-hexadecane were obtained experimentally by analyzing known quantities of the substances. GC analyses were carried out using an HP-5 capillary column (Phenyl Methyl Siloxane 30 m x 320 x 0.25, 100/2.3-30-300/3) and a time program beginning with 2 min at 60 ºC followed by 30 °C/min ramp to 300 °C, then 3 min at this temperature. Flash column chromatography was performed using 230-400 mesh ultra-pure silica gel. NMR spectra were obtained on Bruker AC-300 or on Bruker AMX-500 systems using acetone-d$_6$ and CDCl$_3$ as solvents, with proton and carbon resonances at 300/500 MHz and 75/125 MHz, respectively. Mass spectral data were acquired on a VG AutoSpec mass spectrometer.

Solvents were purified by standard procedures prior to use. Copper salts were dried *in vacuo* at 60 ºC prior to use. O$_2$ was supplied with a purity of 99.99%. All other compounds are commercially available and were used without further purification.

All oxidation reactions involving sodium hypochlorite were carried out with rapid continuous magnetic stirring in Erlenmeyer flasks open to the atmosphere. Sodium hypochlorite was commercial “ultra” laundry bleach containing a stated concentration of 6% NaOCl.

Hydrochloric acid (ca. 1 M) containing 25 wt % of calcium chloride was prepared by dissolving 125 g of anhydrous calcium chloride in 350 mL of water and cooling to room temperature. Once the solution had cooled, 42 mL of concentrated hydrochloric acid were added and the solution was diluted to 500 mL with water.
1. Optimization studies

1.1 Confirmation of Cl₂CHCHCl₂ as source of chlorine

To confirm that the solvent was the source of chlorine in the reactions shown in the Scheme 1 of the manuscript, we replaced Cl₂CHCHCl₂ (Table S1, entry 1) by CICH₂CH₂Cl (DCE, entry 2) as solvent. When the reaction was thus performed in DCE, only 26% of the chlorinated aniline 1-Cl was detected by GC analysis (entry 2). This percentage of chlorinated aniline could be attributed to the 20 mol% of CuCl₂ used as catalyst. Therefore, it was confirmed that tetrachloroethane was serving as the in situ source of the chlorine in our model reaction. In accordance with this hypothesis, in the presence of NCS as chlorinating agent (1.2 equiv), the reactivity was restored and the desired product 1-Cl was obtained with high ortho-regiocontrol after 1 h at 130 °C (entry 3).

1.2 Evaluation of inorganic chlorine sources

Next, a study of the chlorine source was performed using DCE as solvent (Table S2). Unfortunately, inorganic chlorides such as LiCl, NaCl, CsCl or NH₄Cl proved to be inefficient for the ortho-chlorination reaction (entries 2-5). Only upon prolonging the reaction time to 24 h, the ortho-halogenated product 1-Cl could be detected in 16% conversion by GC (18% isolated yield, 78% of the starting material recovered) when LiCl was used (entry 6). As stated before, this percentage of product is attributable to
the 20 mol% of CuCl$_2$ catalyst present, the catalyst acting as the chlorine-source (see also Table S1, entry 2).

### 1.3 Reaction temperature: change from DCE to CH$_3$CN

The temperature was found out to be a critical factor. When we tried to reduce the temperature of the model NCS-chlorination reaction of sulfonamide 1 from 130 °C to 100 °C, we observed that the reaction mixture became heterogeneous. In the search for a more polar solvent to ensure the solubility of all the reactants, MeCN was found to be an optimal solvent for this transformation (Table S3). The results observed in the chlorination of 1 with NCS in MeCN at 130 °C nicely parallels those obtained when using DCE as solvent (entry 1, compare with entry 3 of Table S1). The reaction temperature could be reduced to 100 °C without appreciable changes in reactivity or selectivity (entry 2). However, further decrease of the temperature to 80 °C resulted in a loss of the regiocontrol, affording a mixture of three products (1-Cl, 1-(p)-Cl and 2,4-di-Cl) in similar ratios (entry 3). This result could be rationalized assuming that the Cu-catalyzed directed ortho-chlorination reaction becomes too slow at temperatures below 100 °C, then being competitive the alternative uncatalyzed electrophilic aromatic substitution pathway, thereby resulting in a non-selective transformation.

1.4 Importance of aerobic conditions

Aerobic conditions (O₂ atmosphere) proved to be determinant for achieving high levels of reactivity and selectivity (Table S4). The CuCl₂-catalyzed reaction of the model sulfonamide 1 with NCS under anaerobic conditions (N₂ atmosphere) resulted in a loss of regioselectivity affording a mixture of three products (1-Cl, 1-(p)-Cl and 2,4-di-Cl) (entry 1). This result can be rationalized assuming that O₂ accelerates the Cu-catalyzed ortho-regiocontrolled reaction and, consequently, in its absence the competitive chlorination through a non-catalyzed electrophilic substitution operates in a competitive fashion resulting in mixture of products. In fact, at identical reaction time, the reaction under O₂ provides a higher conversion towards the ortho-chlorinated product with virtually complete regiocontrol (entry 2). Prolonging the reaction time to 1 h under aerobic conditions resulted in full conversion to 1-Cl while maintaining the regiocontrol.
1.5 Use of CuCl₂ as stoichiometric chlorinating agent

As expected, the stoichiometric use of CuCl₂ proved to be an alternative to the use of NCS as the chlorinating agent (see Scheme below). Thus, when the reaction was performed under oxygen atmosphere with stoichiometric amount of CuCl₂ (1.0 equiv) in the absence of NCS under otherwise optimized conditions, the reaction proceeded with very high selectivity to produce the ortho-chlorinated product 1-Cl in a 58% GC-yield.

1.6 Control Experiments: electrophilic halogenations IN THE ABSENCE OF Cu-CATALYST

No reaction was observed in the NCS-halogenation of the deactivated p-CF₃-substituted aniline derivative (3), the starting material being recovered unaltered. Meanwhile, control NBS-halogenations in the absence of Cu-catalysis of substrates with electron-releasing substituents such as the p-MeO- and p-Me-substituted derivatives (2

and 8, respectively) led to very low reactivity and selectivity. In the case of aniline 1, the p-Br derivative was formed with excellent regiocontrol.

**1.7 Bromination of aniline 1**

While the NBS-uncatalyzed bromination of 1 led to the formation of the p-Br derivative with excellent regiocontrol, the CuBr₂-catalyzed NBS-bromination of 1 provided a mixture of o- and p-substitution.

Typical procedure for the N-sulfonylation of anilines

Synthesis of N-phenylpyridine-2-sulfonamide (1).\(^1\) To a solution of aniline (364 \(\mu\)L, 4.00 mmol, 1.00 equiv) in THF (40 mL), pyridine (388 \(\mu\)L, 4.80 mmol, 1.20 equiv) and 2-pyridylsulfonyl chloride (852 mg, 4.80 mmol, 1.20 equiv) were successively added dropwise at 0 °C and under N\(_2\) atmosphere. The mixture was warmed to room temperature and stirred overnight. During this time, a gradual formation of a precipitate was observed. The resulting mixture was then suction filtered through a 6-cm fritted glass funnel (coarse) into a round-bottomed flask, and the filter cake was rinsed with THF (3 x 10 mL). To the resulting filtrate and the washes, water (20 mL) was added and the THF was removed by evaporation at reduced pressure, yielding a suspension of a white solid in the aqueous medium. This solid was collected by filtration, washed sequentially with toluene (2 x 5 mL) and diethyl ether (2 x 5 mL). Then it was transferred to a round-bottomed flask, and dried at 1.0 mmHg to provide 1 as a white powder; yield: 862 mg (92%); mp = 170-172 °C. The analytical data (NMR, HRMS analysis) matched those reported in the literature for N-phenylpyridine-2-sulfonamide [CAS: 103863-00-9].

3. Typical procedure for the synthesis of N-(pyrimidyl)sulfonyl anilines

Synthesis of N-(4-chloro-2-fluorophenyl)pyrimidine-2-sulfonamide (26-Cl). A solution of 2-mercaptopyrimidine (0.561 g, 5 mmol, 1.00 equiv) in a mixture of CH₂Cl₂ (25 mL) and a 1 M solution of HCl having 25 wt % of CaCl₂ (25 mL) was stirred in a 125-mL Erlenmeyer flask for 10 min at −30 to −25 ºC (internal temperature, maintained by intermittent cooling with a dry ice-acetone bath). Then calcium chloride 6-hydrate (19 g) was dissolved in sodium hypochlorite (6% solution, 0.74 M, 24 mL, 18 mmol, 3.3 equiv), and the resulting clear solution was added dropwise with very rapid stirring to the original solution of 2-mercaptopyrimidine while maintaining the internal temperature at −30 to −25 ºC. The resulting mixture was stirred for 15 min at −30 to −25 ºC (internal temperature) before it was diluted with of ice/water (25 mL) and transferred to a separatory funnel (pre-cooled with ice water). The organic phase was rapidly separated and collected in a clean 125-mL Erlenmeyer flask cooled in a dry ice-acetone bath. 2-Chloro-4-fluoroaniline (1.49 mL, 12.5 mmol, 2.5 equiv) was added with stirring, whereupon the mixture became a white suspension. The flask was moved to an ice-water bath and the suspension was stirred for 30 min at 0 ºC. To the resulting suspension was added 1 M phosphoric acid and the organic phase was successively washed with water and brine. The combined organic phase was dried
(MgSO₄) and concentrated under reduced pressure. The residue was purified by flash chromatography (n-hexane-EtOAc 2:1) to afford 26-Cl as a pale yellow solid; yield: 1.15 g (80%); mp = 139-140 °C. ¹H NMR (acetone-d₆, 300 MHz) δ: 8.99 (d, J = 4.8 Hz, 2H), 8.89 (s, 1H), 7.77 (t, J = 4.8 Hz, 1H), 7.66 (dd, J = 9.0, 5.6 Hz, 1H), 7.29 (dd, J = 8.4, 2.9 Hz, 1H), 7.13 (ddd, J = 9.0, 8.0, 2.9 Hz, 1H). ¹³C NMR (acetone-d₆, 75 MHz) δ: 166.5, 161.1 (d, J_{C-F} = 246.7 Hz), 159.7, 131.7, 130.8 (d, J_{C-F} = 10.7 Hz), 129.2 (d, J_{C-F} = 8.9 Hz), 124.9, 117.6 (d, J_{C-F} = 26.2 Hz), 115.5 (d, J_{C-F} = 22.4 Hz). ¹⁹F NMR (acetone-d₆, 282 MHz) δ: 61.9. ### 5.3. METHOD C: ortho-Bromination using NBS as a source of bromine

An oven-dried, nitrogen-flushed 20 mL vessel was charged with the corresponding N-protected aniline (2-3, 8-17, 22 and 23) (0.20 mmol, 1.00 equiv), NBS (42.7 mg, 0.24 mmol, 1.2 equiv) and CuBr₂ (4.47 mg, 0.02 mmol, 10 mol%). oxygen three times. Under the atmosphere of oxygen, MeCN (1 mL) and the internal standard \textit{n}-hexadecane (50 µL) were added \textit{via} syringe. **5.4. METHOD D: N-(2-pyrimidyl)sulfonyl-directed copper-catalyzed ortho-chlorination**

An oven-dried, nitrogen-flushed 20 mL vessel was charged with the corresponding N-(pyrimidyl)sulfonyl aniline (26, 26-Cl, 27-30) (0.20 mmol, 1.00 equiv), NCS and CuCl$_2$ (8.1 mg, 0.06 mmol, 30 mol%). The reaction vessel was
sealed with a Teflon lined cap, then evacuated and flushed with oxygen three times. Under the atmosphere of oxygen, the solvent (1 mL) and the internal standard n-hexadecane (50 µL) were added via syringe. The resulting mixture was stirred at the appropriate temperature 16 h. The solvent used [MeCN or DMF (1.00 mL)], the temperature (130 °C or 150 °C) and the exact amount of NCS would be specified in each case. After the reaction was complete, the volatiles were removed in vacuo and the residue was purified by column chromatography (n-hexane-EtOAc 2:1), yielding the corresponding N-(2-chlorophenyl)pyrimidine-2-sulfonamides.

6. Mechanistic Investigations
6.1. Intramolecular isotopic kinetic effect

a) Synthesis of the deuterated aniline derivative 1(D).

![Chemical structure of the synthesis of 1(D)]
Following the literature procedure, 1.00 g (5.82 mmol) of 2-bromoaniline was treated with several portions of MeOD to give 2-bromoaniline-d$_2$ (amino group exchange). The 2-bromoaniline-d$_2$ was the added to 2.0 g (0.03 mmol) of zinc dust in 20 mL of 10% NaOD in D$_2$O and the slurry heated under reflux for 72 h, after which time the 2-deuteroaniline was isolated as a colorless oil, after filtration, extraction and drying.

Following the typical procedure for N-sulfonylation, pyridine (388 µL, 4.80 mmol, 1.20 equiv) and 2-pyridylsulfonyl chloride (852 mg, 4.80 mmol, 1.20 equiv) were successively added dropwise at 0 ºC to a solution of 2-deuteroaniline (364 µL, 4.00 mmol, 1.00 equiv) in THF (40 mL), under N$_2$ atmosphere. The mixture was warmed to room temperature and stirred overnight. During this time, a gradual formation of a precipitate was observed. The resulting mixture was then suction filtered through a 6-cm fritted glass funnel (coarse) into a round-bottomed flask, and the filter cake was rinsed with THF (3 x 10 mL). To the resulting filtrate and the washes, water (20 mL) was added and the THF was removed by evaporation at reduced pressure, yielding a suspension of a white solid in the aqueous medium. This solid was collected by filtration, washed sequentially with toluene (2 x 5 mL) and diethyl ether (2 x 5 mL). Then it was transferred to a round-bottomed flask, and dried at 1.0 mmHg to provide 1(D) as a white powder; yield: 862 mg (92%); mp = 170-172 ºC. $^1$H NMR (acetone-d$_6$, 300 MHz) δ: 9.23 (s, 1H), 8.68 (dt, $J = 4.7$, 1.3 Hz, 1H), 8.10 – 7.92 (m, 2H), 7.58 (ddd, $J = 7.2$, 4.8, 1.6 Hz, 1H), 7.37 – 7.16 (m, 3H), 7.11 – 6.98 (m, 1H). $^{13}$C NMR (acetone-d$_6$, 75 MHz) δ: 158.0, 150.9, 139.1, 138.6, 129.8, 129.7, 127.9, 125.2, 123.5, 121.9, 121.8. ESI$^+$ calcd. for C$_{11}$H$_{10}$DN$_2$O$_2$S (M+H)$^+$: 235.0535; Found: 235.0537.

b) Determining the intramolecular isotopic kinetic effect when using (Cl$_2$CH)$_2$

An oven-dried, nitrogen-flushed 20 mL vessel was charged with the deuterated aniline derivative 1(D) (0.20 mmol) and copper(II) chloride (5.38 mg, 0.04 mmol,

20 mol%). The reaction vessel was sealed with a Teflon lined cap, then evacuated and flushed with oxygen three times. Under the atmosphere of oxygen, Cl₂CHCHCl₂ (1 mL) and the internal standard n-hexadecane (50 μL) were added via syringe. After stirring the reaction mixture at 130 °C for 38 h, it was diluted with 5 mL of CH₂Cl₂ and filtered through a pad of Celite. The filtrate was washed twice with brine. The organic layer was dried over Na₂SO₄ and concentrated under vacuum. The residue was purified by column chromatography (SiO₂, n-hexane-ethyl acetate 5:1), yielding a mixture of 1-Cl and 1(D)-Cl in a ratio 1:1. The GC analysis showed that the conversion was 65% and the ratio of ortho-proton product (1-Cl) to ortho-deuterium product (1(D)-Cl) is 1:1 as deduced from the comparison with the standard ¹H NMR spectrum of 1-Cl: the integration of the peak at the multiplet at 7-68-7.62 ppm was 1.5 instead of 2.

c) Determining the intramolecular isotopic kinetic effect when using NCS

An oven-dried, nitrogen-flushed 20 mL vessel was charged with the corresponding N-protected aniline (1(D)) (0.20 mmol, 1.00 equiv), NCS (32.0 mg, 0.24 mmol, 1.2 equiv) and CuCl₂ (2.69 mg, 0.02 mmol, 10 mol%). The reaction vessel was sealed with a Teflon lined cap, then evacuated and flushed with oxygen three times. Under the atmosphere of oxygen, MeCN (1 mL) and the internal standard n-hexadecane (50 μL) were added via syringe. The resulting mixture was stirred at 100 °C for 1 h. After the reaction was complete, the volatiles were removed in vacuo and the residue was purified by column chromatography (n-hexane-EtOAc 5:1), yielding a mixture of 1-Cl and 1(D)-Cl in a ratio 1:1. The GC analysis showed that the conversion was 65% and the ratio of ortho-proton product (1-Cl) to ortho-deuterium product (1(D)-Cl) is 1:1 as we can deduced from the comparison with the standard ¹H NMR spectrum of 1-Cl: the integration of the peak at the multiplet at 7-68-7.62 ppm was 1.5 instead of 2.

7. Typical procedure for the Mg-promoted N-desulfonylation

Synthesis of 2-chloroaniline (31). To a solution of N-(2-chlorophenyl)pyridine-2-sulfonyamide 1-Cl (53.5 mg, 0.2 mmol, 1.00 equiv) in dry MeOH (10 mL) was added magnesium (turnings, 48.6 mg, 2.00 mmol, 10 equiv). The reaction mixture was sonicated at room temperature until complete conversion of the starting material (TLC monitoring). Equal volumes of diethyl ether and saturated aq. NH\textsubscript{4}Cl were added, and the organic phase was separated. The aqueous phase was extracted with diethyl ether (2 x 10 mL) and the combined organic phases were dried (MgSO\textsubscript{4}) and concentrated to dryness to give pure 31 as colourless oil; yield: 22.0 mg (85%). The analytical data (NMR, GC-MS analysis) are in agreement with those of the commercial available 2-chloroaniline [CAS: 95-51-2].

9. **Regioselectivity in the ortho-chlorination process**

In order to ensure the correct regio-position of the new halogen-carbon bond, a series of para-substituted anilines bearing a chlorine in the ortho- or meta-position were N-protected with (2-pyridyl)sulfonyl chloride. Thus, 2-chloro-4-iodoaniline, 2-chloro-4-fluoraniline and methyl 4-amino-3-chlorobenzoate were derivatized to the corresponding protected substrates \(36, 37\) and \(38\), respectively (vide infra). The NMR spectra recorded for the corresponding \(N\)-(2-pyridyl)sulfonyl anilines matched those reported for the Cu-catalyzed ortho-chlorinated products.

For the non-commericially available ortho-chloro anilines, the meta-regioisomer was \(N\)-protected with (2-pyridyl)sulfonyl chloride. This is the case for 3-chloro-4-methoxyaniline (substrate \(39\)), 3-chloro-4-iodoaniline (\(20\)), 4-bromo-3-chloroaniline (\(21\)) and 3,4-dichloroaniline (\(22\)). The NMR spectra recorded for the corresponding \(N\)-(2-pyridyl)sulfonyl anilines did not match those reported for the Cu-catalyzed ortho-chlorinated products. Anilines \(20, 21\) and \(22\) have been already described because they were used as starting materials. The corresponding \(^1\)H NMR spectra of both regioisomers, ortho- and meta-, can be compared in NMR spectra section, see pp. S137-S144.
