22- $^1$H and $^{13}$C NMR spectra for cycloadducts 14, 21-23, 25 and $^1$H NMR for cycloadduct 20
7.1 General Procedures

All air- and/or moisture-sensitive reactions were carried out under an argon atmosphere in oven-dried glassware. Commercially available reagents were used without further purification, apart from the following: trimethylacetyl chloride was distilled from anhydrous P_2O_{10}, Et_3N was distilled over KOH pellets, t-BuOK was dried under vacuum at 50 °C overnight before use. 40-60 Petroleum ether was redistilled before use and refers to the fraction of light petroleum ether boiling in the range 40-60 °C. Benzene was dried over 4 Å molecular sieves. All other solvents were obtained dried using an Innovative Technology Solvent Purification System (SPS).

Analytical thin layer chromatography (TLC) was performed using commercially available aluminium-backed plates coated with silica gel 60 F_{254} (UV_254) or neutral aluminium oxide 60 F_{254} (UV_254), and visualised under ultra-violet light (at 254 nm), or through staining with ethanolic phosphomolybdic acid followed by heating. Flash column chromatography was carried out using 200-400 mesh silica gel 40-63 µm or neutral alumina.

Melting points were determined either using Thermo Scientific 9100 or Gallenkamp melting point apparatus and are uncorrected. Gas Chromatography was carried out on a Hewlett-Packard 5890 series II gas chromatograph fitted with a 25 cm column and connected to a flame ionisation detector. Infrared spectra were recorded using a Diamond ATR (attenuated total reflection) accessory (Golden Gate) or as a solution in chloroform via transmission IR cells on a Perkin-Elmer FT-IR 1600 spectrometer. ^1H, ^13C, ^19F, and ^29Si NMR spectra were recorded in CDCl_3 (unless otherwise stated) on Varian Mercury-200 (^1H), Varian Mercury-400 (^1H, ^13C, ^19F), Bruker Avance-400 (^1H, ^13C, ^29Si), Varian Inova-500 (^1H, ^13C, ^29Si) or Varian VNMRS-700 (^1H, ^13C, ^29Si) spectrometers and reported as follows: chemical shift δ (ppm) (number of protons, multiplicity, coupling constant J (Hz), assignment). All ^13C NMR spectra were proton decoupled. The chemical shifts are reported using the residual signal of CHCl_3 as the internal reference (δ_H = 7.27 ppm; δ_C = 77.0 ppm). All chemical shifts are quoted in parts per million relative to tetramethylsilane (δ_H = 0.00 ppm) and coupling constants are given in Hertz to the nearest 0.5 Hz. Assignment of spectra was carried out using COSY, NOESY, HSQC, and HMBC experiments. Gas-Chromatography mass spectra (EI) were taken using a Thermo-Finnigan Trace with a 25 cm column connected to a VG Mass Lab Trio 1000. Electrospray mass spectra (ES) were obtained on a Micromass LCT Mass Spectrometer. High resolution mass spectra were obtained using a Thermo-Finnigan LTQFT mass spectrometer or Xevo QToF mass spectrometer (Waters UK, Ltd) by Durham University Mass Spectrometry service, or performed by the EPSRC National Mass Spectrometry Service Centre, University of Wales, Swansea.

Standard procedure for the Mitsunobu reaction
THF was added in one portion to triphenylphosphine, and alcohols at 25 °C under argon. The reaction vessel was then sonicated for a few minutes (approx. 5 min) giving a homogenous solution. To the sonicated reaction mixture azodicarboxylate ester was added dropwise over the course of 5-15 min. The reaction mixture was sonicated for 15 min and subsequently triturated with hexane to remove the
majority of the triphenylphosphine. Flash column chromatography on silica, elution gradient 0 to 30% ethyl acetate in pet. ether, afforded the desired product.

**Standard ester hydrolysis procedure (B)**

To a solution of ester in THF was added a solution of lithium hydroxide (2 eq) in water. The reaction mixture was stirred at 50 °C for 30 h. The reaction was then quenched by addition of HCl (5 M, pH = 1) and diluted with Et₂O. The aqueous layer was separated and extracted three times with Et₂O. The combined organic layers were dried over MgSO₄, filtered, and concentrated in vacuo. Flash column chromatography on silica, elution gradient 0 to 50% ethyl acetate in pet. ether, afforded the desired carboxylic acid.

**Standard procedure for acylpolysilane synthesis (C)**

*Stage 1*

Tetrakis(trimethylsilyl)silane and dry potassium tert-butoxide were dissolved in THF and stirred for 3 h at room temperature. The resulting solution was used in *Stage 2.*

*Stage 2*

A solution of carboxylic acid in DCM was treated with oxalyl chloride and DMF (one drop) at 0 °C. The reaction mixture was stirred at that temperature for 3 h after which time volatiles were evaporated in vacuo. The residue was redissolved in THF and treated with silyl potassium (*Stage 1*) at -78 °C. After stirring for 3 h at -78 °C saturated ammonium chloride solution was added. The organic layer was separated, and the aqueous layer was extracted three times with Et₂O. The combined organic layers were dried over MgSO₄, filtered, and concentrated in vacuo. Flash column chromatography, elution gradient 0 to 20% diethyl ether in pet. ether, afforded the desired product.
