Electronic Supporting Information

DNA-Directed Growth of Ultrafine CoAuPd Nanoparticles on Graphene as Efficient Catalysts for Formic Acid Dehydrogenation

Zhi-Li Wang, Hong-Li Wang, Jun-Min Yan,* Yun Ping, Song-Il O, Si-Jia Li, and Qing Jiang

Key Laboratory of Automobile Materials, Ministry of Education, Department of Materials Science and Engineering, Jilin University, Changchun 130022, China.
Chemicals

Formic acid (HCOOH, FA, Sigma-Aldrich, 96%), graphite flake (C, Alfa Aesar, 325 mesh, 99.8%), deoxyribonucleic acid (DNA, Sinopharm Chemical Reagent Co., Ltd, >85%), sodium tetrachloropalladate (II) (Na₂PdCl₄, Sinopharm Chemical Reagent Co., Ltd, Pd >36.4%), tetrachloroauric (III) acid (HAuCl₄·4H₂O, Sinopharm Chemical Reagent Co. Ltd, Au >47.8%), cobalt (II) chloride hexahydrate (CoCl₂·6H₂O, Sinopharm Chemical Reagent Co., Ltd, >99%), sulfuric acid (H₂SO₄, Beijing Chemical Works, 98%), potassium permanganate (KMnO₄, Sinopharm Chemical Reagent Co. Ltd, >99%), hydrogenperoxide (H₂O₂, Beijing Chemical Works, 30%), hydrochloric acid (HCl, Beijing Chemical Works, 36%~37%), phosphoric acid (H₃PO₄, Sinopharm Chemical Reagent Co. Ltd, >85%), polyvinylpyrrolidone K30 (PVP, (C₆H₉NO)n, Mw: av. 58000 g/mol, Beijing Chemical Works), and hexadecyltrimethyl ammonium bromide (CTAB, Aladdin Chemistry Co., Ltd, >99%) were used without further purification. De-ionized water with the specific resistance of 18.2 MΩ·cm was obtained by reversed osmosis followed by ion-exchange and filtration.

Synthesis of graphene oxide (GO)

GO was synthesized from graphite by a modified Hummers’ method. Briefly, a mixture of graphite powder (3.0 g) and KMnO₄ (18.0 g) was put into the H₂SO₄/H₃PO₄ (360/40 mL) solution. Then, the above graphite suspension was stirred and heated to 323 K for 12 h. After the graphite suspension was cooled to room temperature, it was poured onto ice (600 mL) and followed by addition of H₂O₂ (4.0
mL). The suspension was then filtered by using a 0.2 micron Nylon Millipore filter, and washed with 5% HCl solution and water. Finally, GO (0.2 wt%) was achieved by ultrasonication of the washed suspension for 40 min.

**Synthesis of CoAuPd/DNA-rGO composite**

A facile two-step method is employed for preparing CoAuPd/DNA-rGO composite. In the first step, 10.0 mg of DNA is added into 30.0 mL of homogeneous GO aqueous dispersion (1.5 mg mL$^{-1}$) and sonicated for 2 h, followed by heating at 368 K for 10 min. In the second step, 5.0 mL of aqueous solution containing CoCl$_2$ (5.0 mM), HAuCl$_4$ (5.0 mM), and Na$_2$PdCl$_4$ (5.0 mM) is mixed with the above DNA-GO suspension, and then an aqueous NaBH$_4$ solution (5.0 mL, 300.0 mM) is added into the above mixture under magnetic stirring for 90 min. The product was separated by centrifugation, washed with water for several times, and re-dispersed into 5.0 mL of water for the following catalytic reaction.

For comparison, CoAuPd/rGO composite, CoAuPd NPs, CoAuPd/C, CoAuPd/PVP-rGO (PVP: 10.0 mg), and CoAuPd/CTAB-rGO (CTAB: 10.0 mg) catalyst are also prepared as the same method mentioned above. All catalysts are prepared under same experimental conditions, including the amount of GO, metal precursors, the reaction temperature, reaction time, and stirring speed.

**Characterizations**

Powder X-ray diffraction (XRD) was performed on a Rigaku RINT-2000 X-ray diffractometer with Cu Kα. Transmission electron microscope (TEM, Tecnai F20,
Philips) and corresponding energy-dispersive X-ray (EDX) spectrometry were applied for the detailed microstructure and composition analyses, and the amorphous carbon coated copper grids were used as the sample supporter. X-ray photoelectron spectrometry (XPS) was carried out on an ESCALABMKLL X-ray photoelectron spectrometer by using an Al Kα source. Raman spectrum was collected on a micro-Raman spectrometer (Renishaw) with a laser of 532 nm wavelength. Ultraviolet-visible (UV-Vis) absorption spectra were recorded on an Agilent Cary 50 spectrophotometer in the wavelength range of 200-700 nm. Detailed analyses for CO₂, H₂ and CO were performed on GC-7900 with thermal conductivity detector (TCD) and flame ionization detector (FID)-Methanator (detection limit for CO: ~10 ppm).

Catalytic activities for the dehydrogenation of FA

Typically, the aqueous solution (5.0 mL) containing CoAuPd/DNA-rGO composite (n_{metal} = 0.06 mmol) was kept in a two-necked round-bottom flask. One neck was connected to a gas burette, and the other was connected to a pressure-equalization funnel to introduce FA aqueous solution (1.0 M, 5.0 mL). The catalytic reaction begun after the FA solution was added into the flask with magnetic stirring (600 r min⁻¹). A graduated glass tube filled with water was connected to the reaction flask to measure the volume of the gas (absolute volume = observation volume - blank volume) that evolved from the reaction. The reactor was immersed in a water bath to stabilize the temperature at 298 K.

The catalytic activities of other catalysts for FA decomposition were also applied
as the above method. The molar ratios of metal:FA ($n_{\text{metal}}/n_{\text{FA}}$) for all the catalytic reactions were kept as a constant of 0.012. All experiments were repeated at least two times. The experiments showed repeatable results.

**Calculation methods:**

\[
R_{\text{initial} \ H_2} = \frac{1}{2} \frac{V_{\text{gas}}}{m_{\text{metal}} t} \quad (S1)
\]

Where $R_{\text{initial} \ H_2}$ is the initial rate of $H_2$ generation, $m_{\text{metal}}$ is the weight of the metallic catalyst, and $t$ is the reaction time of 20 min.

\[
\text{TOF}_{\text{initial}} = \frac{P_{\text{atm}} V'_{H_2}}{n_{\text{metal}} t} \quad (S2)
\]

Where $\text{TOF}_{\text{initial}}$ is initial turnover frequency, $V'_{H_2}$ is the generated volume of $H_2$ during the first 20 min of the reaction, $n_{\text{metal}}$ is the mole number of the metallic catalyst and $t$ is the reaction time of 20 min.
