General methods

All chemicals were purchased from commercial suppliers and used without further purification. Anhydrous solvents were used to carry out organic reactions under inert argon or nitrogen environment. $^1$H NMR and $^{13}$C NMR spectra were recorded on a Varian Inova-600 spectrometer or a Bruker Avance-800 spectrometer. $^{19}$F NMR spectra were recorded on a Varian Mercury-300 spectrometer. MALDI-TOF analysis of samples was carried out using an Applied Biosystems 4700 MALDI TOF/TOF with each reaction mixture ($0.5 \mu$L) diluted 100 fold using a solvent mixture (H$_2$O:MeOH:TFA = 50:50:0.1, by volume). The diluted reaction mixture ($0.5 \mu$L) was mixed with the same volume of 2,5-dihydroxybenzoic acid solution (10 mg/mL in 50% of acetonitrile in water) on a well spot of a stainless steel plate (ABI 01-192-6-AB). The glycans were analyzed in the positive ion reflector mode with a 355 nm (200 Hz) Nd:YAG laser. The instrument was calibrated with ABI peptide standards (4700 Mass standards kit, 4333604). Spectra were analyzed using the GPS Explorer software (v. 3.0) (Applied Biosystems). High resolution electrospray ionization (HR-ESI) mass spectra were obtained using Thermo Electron LTQ-Orbitrap Hybrid MS at the Mass Spectrometry Facility in the University of California, Davis. Silica gel 60 Å (200–425 mesh, Fisher Chemical) was used for flash column chromatography. Thin-layer chromatography (TLC) was performed on silica gel plates 60 GF254 (Sorbent technologies) using $p$-anisaldehyde sugar stain or 5% sulfuric acid in ethanol stain for detection.

Small scale one-pot multienzyme (OPME) glycosylation reactions

**α2–3-Sialylation**

PmST1 E271F/R313Y mutant (0.07 µg) was added to a 0.5 mL centrifuge tube containing 0.01 µmol of a lactoside acceptor (chosen from 1–8), Neu5Ac (1.2 eq.), CTP (2 eq.), Tris-HCl buffer (100 mM, pH 8.5), MgCl$_2$ (20 mM), NmCSS (0.08 µg), and water (total volume = 10 µL). The reactions were monitored by TLC (EtOAc:MeOH:H$_2$O:AcOH = 5:2:1:0.1).

**α2–6-Sialylation**

Pd2,6ST (0.72 µg) was added to a 0.5 mL centrifuge tube containing 0.01 µmol (1 eq.) of a lactoside acceptor (chosen from 1–8), Neu5Ac (1.2 eq.), CTP (2 eq.), Tris-HCl buffer (100 mM, pH 8.5), MgCl$_2$ (20 mM), NmCSS (0.08 µg), and water (total volume = 10 µL). The reactions were monitored by TLC (EtOAc:MeOH:H$_2$O:AcOH = 5:2:1:0.1).

**α1–3-Galactosylation**

α1–3GalT (0.4 µg) was added to a 0.5 mL centrifuge tube containing 0.01 µmol (1 eq.) of a lactoside acceptor (chosen from 1–8), galactose (1 eq.), ATP (2 eq.), UTP (2 eq.), MgCl$_2$ (20 mM), MnCl$_2$ (20 mM), Tris-HCl buffer (100 mM, pH = 7.0), *E. coli* GalK (1.75 µg), BLUSP (4.3 µg), PmPpA (5.0 µg), and water (total volume = 10 µL). The reactions were monitored by TLC (EtOAc:MeOH:H$_2$O:AcOH = 5:2:1:0.1).

**TLC-ImageQuant verification of reaction conversion rates**

Reaction conversion rates were determined by staining the TLC plates with p-anisaldehyde sugar stain and then using ImageQuant 5.2 software to compare the relative intensities between the glycosylation product spot and the lactoside acceptor spot of each reaction (Figure S1). For external standard comparison, each lactoside acceptor spot was also compared with its corresponding standard 10 mM stock solution spot to verify the conversion rates of each reaction.

Fluorous solid-phase extraction (FSPE) cartridge purification

For fluorous-solid phase extractions, the chemical reaction mixtures were directly loaded to FluoroFlash® SPE cartridges (2 g fluorous silica gel in 10 mL cartridge, conditioned with deionized water) (Fluorous Tech. Inc.) and washed with deionized water (3 mL × 4) to remove non-fluorous reaction components. The fluorous-tagged products were eluted with methanol (3 mL × 4). For enzymatic reactions, the reaction mixtures were centrifuged at 13,226 × g for 10 min. to remove precipitates. Next, the supernatants were loaded to the conditioned FSPE cartridges and the cartridges were then washed with deionized water (3 mL × 4) to remove non-fluorous components. Lastly, the fluorous-tagged products were eluted by the following washes of methanol (3 mL × 4).

Figure S1. Reaction conversion rates of Table 1 and Table 2 were determined by first staining the TLC plates with \( p \)-anisaldehyde sugar stain and then using ImageQuant 5.2 to compare the relative intensities (under greyscale) between the glycosylation product spot and the lactoside acceptor spot of each reaction. For external standard comparison, each lactoside acceptor spot was also compared with its corresponding standard 10 mM stock solution spot (of compounds 2–8) to verify the conversion rates of each reaction.

After loading the reaction mixture to FSPE cartridge, 3 × 3.5 mL of H₂O (numbers 1–3) was used to wash out non-fluorous components of the mixture. 3–4 × 3.5 mL of MeOH (numbers 4–7) was then used to elute the fluorous-tagged glycans. As shown on thin-layer chromatography (TLC) plates, the C₃F₇-tagged sialoside was not retained in the cartridge during the third water wash and eluted prematurely prior to the methanol wash. Developing solvent used for TLC was EtOAc:MeOH:H₂O = 5:2:1 by volume.

After loading reaction mixtures to FSPE cartridges, 4 × 3.5 mL of H₂O was used to wash out non-fluorous components of the mixture (numbers 1-4). 3–5 × 3.5 mL of MeOH was then used to elute the fluorous-tagged glycans (numbers 5–9).
