1. Experimental details

1.1 Preparation of C₃N₄-PEDOT composites

The g-C₃N₄ powders are prepared via polycondensation of dicyandiamide according a reported method.¹ In a typical synthesis, dicyandiamide powder was placed in an alumina crucible, covered with cap and heated at 550 °C for 4 h in a muffle furnace with a ramp rate of 2.3 °C/min and in the cooling process the ramp rate was maintained at 1 °C/min. The obtained yellow agglomerates were ground to fine powders in an agate mortar for later use.

To prepare the C₃N₄-PEDOT composites, the g-C₃N₄ powders were mixed with commercial PEDOT-PSS “solution” containing 0.5 wt%, 1 wt%, 2 wt% and 5 wt% of PEDOT-PSS respectively. The suspension was then evaporated under vigorous stirring via heating. To make the PEDOT insoluble, the dried powders were subsequently soaked in ethylene glycol (EG) and stirred for 1 hour. After treatment with EG, the C₃N₄-PEDOT composites were centrifuged, washed with deionized water and ethanol for several times and dried in a 100 °C oven. The final products were ground again after being dried, and different composites were denoted as C₃N₄-0.5 wt% PEDOT, C₃N₄-1 wt% PEDOT, C₃N₄-2 wt% PEDOT and C₃N₄-5 wt% PEDOT, respectively.

1.2 Characterization of photocatalysts

The prepared C₃N₄-PEDOT composites were comprehensively characterized by powder X-ray diffraction (XRD, Rigaku Miniflex) with Co Kα (λ= 1.78897 Å)
radiation, UV-Vis spectrometer (Shimadzu 2200), X-ray photoelectron spectroscopy (XPS, Thermo Escalab 250, a monochromatic Al KR x-ray source), Fluorescence spectrometer (FLS 920, Edinburgh Instruments), and transmission electron microscopy (TEM, Philips Tecnei F20).

1.3 Photocatalytic reactions

The photocatalytic reactions were carried out in a quartz reactor connected to a closed gas circulation and evacuation system. In a typical reaction, 100 mg catalyst was suspended in 300 mL aqueous solution containing 30 mL triethanolamine (TEA) solution, and H$_2$PtCl$_6$ solution containing 1 wt% of Pt was added. Before the reaction started, the whole system was thoroughly degassed. The quartz reactor was then irradiated by a 300 W Xe lamp (Beijing Trusttech Co. Ltd., PLS-SXE-300UV) equipped with an optical cut-off filter (λ > 400 nm) to remove ultraviolet light and a water filter to eliminate infrared light. The temperature of the reactor was maintained at 293±5 K by a cooling water cycle system during the reaction. The amount of H$_2$ produced was analyzed using gas chromatography (GC) with Ar as the carrier gas.
2. Results of Characterizations
