1. General Experimental Details

All rhodium (III) catalysed reactions were undertaken in oven dried (~80 °C) reaction vessels with Teflon screw caps under an atmosphere of air, using anhydrous solvents. The reaction is insensitive to atmospheric moisture, and oven drying was primarily for convenience. All commercial reagents were used as supplied.

Reaction solvents were dried using distillation over an appropriate drying agent or stored over molecular sieves from purchase: THF (Sodium), CH₂Cl₂ (CaH₂), DCE (molecular sieves). All solvents used for purification were distilled. Column chromatography was carried out using 40-63 mesh silica gel. Routine TLC analysis was carried out on aluminum sheets coated with silica gel 60 F254, 0.2 mm thickness. Plates were viewed using a 254 nm ultraviolet lamp or developed using KMnO₄.

NMR-spectra were recorded on a 300 or 400 MHz spectrometers with chemical shifts (δ) being reported in ppm relative to residual chloroform (¹H = 7.26 or ¹³C = 77.2), Coupling constants (J) are quoted in Hertz (Hz). High-resolution mass spectra were obtained using ESI unless otherwise noted. Infra-red spectra were recorded neat using FT/IR spectrometers. GCMS retention times are quoted in minutes for the method “(50_40)”: injection temperature 50°C, hold T for 3 min, ramp 40°C/min, final temperature 280 °C, hold T for 3 minutes.

2.2 Additive Screen

Whilst investigating the alkynylation of arene 2 we undertook an extensive screen of additives. All reactions were performed under an atmosphere of air using the reported conditions on a 0.03 mmol scale in a multiwall plate. Unfortunately all experiments were unsuccessful with regard to increasing the yield of alkynylated compound 3. A list of additives screened is given below:

PIDA (0.5 eq)
TsOH (0.5 eq)
PIDA and TsOH (0.5 eq each)
AcOH (0.5 eq)
AuCl (0.1 eq)
TFA (1.2 eq)
AuCl (0.1 eq) and TFA (1.2 eq)
TIPSCI (1 eq)
LiCl (1 eq)
LiCl (2 eq)

2.3 Re-optimization for substrate 4a

For substrate 4a we were able to show that reaction proceeds equally well in DCE or DCM at 60 °C with 5 mol% catalyst loading. Unfortunately when these conditions were applied in the preparation of 5g and 5i the yields were 13% and 20% respectively (compared to 45% and 84% for the reported conditions), and hence these conditions were not explored any further. We also demonstrated that using 1.5 equivalents of 1 (81% yield) and a single equivalent (57% yield) was detrimental to the reaction.
3. Synthesis and Characterization Data

3.1 Substrate Preparation

Substrates previously reported by the Glorius group were prepared using the established procedures.¹,²

**General procedure for synthesis of cinnamic amide substrates**

All reactions were carried out in oven-dried glassware, under an atmosphere of argon and using dried solvents.

To a solution of cinnamic acid (3.00 mmol, 1.00 eq) and N,N-dimethylformamide (346 µL, 4.50 mmol, 1.5 eq) in CH₂Cl₂ (6.0 mL) at 0 °C was added drop wise oxalylchloride (256 µL, 2.94 mmol, 0.98 eq). The solution was stirred at room temperature for 4 h prior to the addition of diisopropylamine (953 µL, 6.75 mmol, 2.25 eq) as a solution in CH₂Cl₂ (13.5 mL) in one portion. The resulting mixture was stirred for at least 2 h (monitor by TLC) at room temperature and then filtered through a short plug of silica. The organic phase was washed with aqueous NaOH (2N, 20 mL), aqueous HCl (1N, 20 mL) and saturated aqueous NaCl (20 mL), dried (MgSO₄), concentrated *in vacuo* then and purified.

3.2 Catalysis Reactions

**General procedure for the alkynylation of alkenes and arenes**

To a solution of cinnamic amide or benzamide (0.200 mmol, 1.0 eq) and RhCp*(MeCN)₃(SbF₆)₂ (17 mg, 10 mol%) in DCM (1.5 mL) was added TIPS-EBX 1 (171 mg, 0.400 mmol, 2.0 eq) and the reaction stirred for 16 h at 80 °C. After cooling, the reaction was filtered through a short plug of silica and then purified. **Note:** Reactions should be heated directly after the addition of 1 or a decrease in yield is observed.

4. Robustness Screen results

A simplified robustness screen as recently reported\(^4\) has been undertaken to evaluate the tolerance of this reaction to the given functionalities and chemical motifs, as well as the stability of these ‘additives’ to the reaction conditions. This procedure requires the undertaking of a standard reaction in the presence of one molar equivalent of a given additive (functional group or heterocycle). After the pre-determined reaction time, the yield of the product, the starting material remaining, and the additive remaining is determined by GC analysis.

The calibration of the additives, starting materials and the product of the reaction was undertaken using the single point calibration technique for gas chromatography (GC) analysis as previously described. Evaluation of two groups of additives, ‘functional groups’ (Group A) and ‘heterocycles’ (Group B) as previously reported was undertaken.

Excluding reaction time and GC running time, the whole screen was undertaken in approximately 8 h including control experiments and analysis.

The standard reaction evaluated.

Sample procedure:

1) To 11 oven-dried Schlenk flasks under air was added RhCp*(MeCN)\(_3\)(SbF\(_6\)) (0.01 mmol, 8 mg, 10 mol%).

2) A stock solution of \(N,N\)-diisopropylcinnamamide 4 (1.20 mmol, 276 mg, 1 eq.), \((12 \times 0.100 \text{ mmol} = 1.20 \text{ mmol scale})\) in \(\text{CH}_2\text{Cl}_2\) (9.0 mL) was prepared, and the mixture stirred until complete dissolution of the reagent had occurred.

3) A portion of the stock reaction mixture (0.75 mL, \(\sim 0.100 \text{ mmol}\)) was then added \textit{via} syringe (1 mL) to each Schlenk flask containing the catalyst. The corresponding additive (0.100 mmol) followed immediately by TIPS-EBX 4 (86 mg, 0.200 mmol, 2 eq) was added to each reaction vessel, the vessel sealed and then the heated directly for 16 h at 80 °C in an oil bath.

4) Once cooled, mesitylene (28 \(\mu\text{L}, 0.200 \text{ mmol}, 1 \text{ eq}\)) was added to each reaction, and analysis by GC was undertaken.

Note:

- Change in volume of stock solution due to addition of starting materials was not accounted for, hence a control reaction (no additive) is undertaken to determine the maximum yield of reaction in the screen.
- \textit{N-methylimidazole} and \textit{dodecylamine} should be filtered through Celite and not silica when preparing samples for GC analysis.
- Following the original screen 5 reactions were repeated to ensure consistency and reproducibility of the data.
Table 1. Table shows the affect of a given additive on the standard reaction. The yield of 5a, and the additive and starting material 4a remaining after reaction are given. Color-coding should help the ready assessment of the data: green (above 66%), yellow (34-66%), red (below 34%). All yields are GC yields. SM is starting material. Yields in parenthesis are of the control group: selected experiments were repeated to ensure consistency and reproducibility of the data.

The screen demonstrated that the reaction was tolerant of an aromatic chloride, nitrile, ester and tertiary amide, with these functionalities showing high stability under reaction conditions. Alkyl chlorides and a terminal olefin were also stable under the reaction conditions and did not inhibit reaction. Aliphatic and aromatic amines, a primary alcohol and a terminal alkyne were all shown to inhibit the reaction. Of the heterocycles screened, azacycles were typically detrimental to the reaction or unstable to the reaction conditions with the exception of 2-chloroquinoline. Furan inhibited the reaction, though benzofuran and thiophene did not, and were stable to the reaction conditions.
