1. Computational Details

Density Functional Theory (DFT) calculations were performed with the Gaussian09 program package,\textsuperscript{[1]} replacing the alkyl groups originally present on compounds TTZ3-5 with methyls to reduce computational effort. Geometry optimization was carried out \textit{in vacuo} using the B3LYP functional\textsuperscript{[2]} and the standard 6-31G* basis set for all atoms. The absorption maximum ($\lambda_{\text{max}}$), vertical excitation energy ($E_{\text{exc}}$) and oscillator strength ($f$) in THF solution were calculated on the optimized structures via time-dependent DFT (TD-DFT) at the CAM-B3LYP/6-31G*\textsuperscript{[3]} level. Solvent effects have been included by using the polarizable continuum model (PCM).\textsuperscript{[4]}

2. General Synthetic Remarks

All air-sensitive reactions were performed under inert atmosphere in a flame- or oven-dried apparatus using Schlenk techniques. Microwave-assisted transformations were carried out using a CEM Discover Bench-Mate reactor at fixed temperature and variable power. Methanol (MeOH) was distilled over metallic magnesium in the presence of a catalytic amount of iodine, while toluene was dried on a resin exchange Solvent Purification System (MBraun). 3,3-Dipentyl-3,4-dihydro-2H-thieno[3,4-b][1,4]dioxepin-6-carbaldehyde (1) was prepared following a reported procedure. 4-(Hexyloxy)-N-(4-(hexyloxy)phenyl)-N-(4-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)phenyl)aniline (10) and 4-(hexylthio)-N-(4-(hexylthio)phenyl)-N-(4-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)phenyl)aniline (11) were prepared according to published procedures or modifications thereof. All other chemicals employed were commercially available and, unless specified, used as received. Petroleum ether was the 40-60 °C boiling fraction. Thin layer chromatography was carried out on aluminum-supported Merck 60 F254 plates; detection was carried out using UV light and permanganate or molybdophosphoric acid solutions followed by heating. Flash column chromatography was performed using Merck Kieselgel 60 (300-400 mesh) as the stationary phase. 1H-NMR spectra were recorded at 300 or 400 MHz, and 13C-NMR spectra were recorded at 75.5 or 100.6 MHz, respectively, on Bruker Avance or Varian Mercury series instruments. Chemical shifts were referenced to the residual solvent peak (CHCl₃, δ 7.26 ppm for 1H-NMR and δ 77.16 ppm for 13C-NMR; C₆D₆ δ 7.16 ppm for 1H-NMR and δ 128.06 ppm for 13C-NMR; THF-d₈ δ 1.72 and 3.58 ppm for 1H-NMR, δ 67.21 and 25.31 ppm for 13C-NMR). FT-IR spectra were recorded with a Perkin-Elmer Spectrum BX instrument in the range 4000–400 cm⁻¹ with a 2 cm⁻¹ resolution. ESI-MS spectra were obtained by direct injection of the sample solution using a Thermo Scientific LCQ-FLEET instrument and are reported in the form m/z (intensity relative to base = 100). UV-Vis spectra were recorded with a Varian Cary 400 spectrometer, and fluorescence spectra were recorded with a Varian Eclipse instrument, irradiating the sample at the wavelength corresponding to maximum absorption in the UV spectrum. Elemental analyses were determined using a CHN-S Flash E1112 ThermoFinnigan Elemental Analyzer; the results were found to be in good agreement with the calculated values. Melting points are uncorrected.

**General procedure for Knoevenagel condensation with cyanoacetic acid**

In a Schlenk flask equipped with a magnetic stirrer aldehyde 7-9 (1.0 eq.) was dissolved in toluene together with cyanoacetic acid (10.0 eq.), ammonium acetate (4.0 eq.), and glacial acetic acid. The reaction mixture was stirred at 110°C for 6 h, then cooled to room temperature and diluted with CHCl₃ (150 mL). The organic phase was washed with a saturated solution of NaHCO₃ (100 mL) and brine (100 mL), and then it was dried with Na₂SO₄. Evaporation of the solvent gave a black solid, which was purified by consecutive washing with ethyl acetate, methanol and pentane and dried under vacuum.

5. Measurement of the Density of Adsorbed Dyes on TiO₂

A transparent nanocrystalline TiO₂ electrode (surface area 0.88 cm²) similar to those used for the photovoltaic measurements (see section n.7) was immersed in 1.0×10⁻⁴ M solutions of dyes TTZ3-5 in THF at rt for 16 h. For each dye, the stained electrode was removed from the solution, dried under a stream of nitrogen and immersed in 10 mL of a 0.1 M KOH solution in THF/MeOH 4:1 at rt until full discoloration was observed (approx. 1 h). The absorbance of the resulting pink-red solution was measured by UV-Vis spectroscopy and compared to that of a standard 8.0×10⁻⁶ M solution of the sensitizer in the same solvent/base mixture. The amount of dye present in the unknown solution was calculated and divided by the electrode surface area, yielding density values of approx. 0.99×10⁻⁷ mol cm⁻², 1.08×10⁻⁷ mol cm⁻² and 1.19×10⁻⁷ mol cm⁻² for compounds TTZ3-5, respectively.
6. **Cyclic voltammetry measurements**

The measurements were carried out in commercially available anhydrous 99.9%, HPLC grade dichloromethane for electrochemistry. The supporting electrolyte used was electrochemical grade \([\text{N(Bu}_4\text{)}_6\text{PF}_6]\). Cyclic voltammetry was performed in a three-electrode C-3 BAS Cell having a glassy carbon working electrode, a platinum counter electrode and the aqueous Ag/AgCl NaCl (3M) reference electrode. A BAS 100A electrochemical analyzer was used as a polarizing unit. Under these experimental conditions, the one-electron oxidation of ferrocene occurs at \(E^{\circ'} = +0.42\) V.

7. DSSC Fabrication and Photoelectrochemical Measurements

Transparent photoanodes for DSSCs were prepared by screen-printing a commercial TiO$_2$ paste (Dyesol 18NR-T) on a 8Ω/sq conductive glass substrate (Pilkington), and by sintering the resulting electrodes at 520 °C for 30 minutes. After sintering, the thickness of the semiconductor layer was measured by means of a profiler (Dektak 150, Veeco) and determined to be 5.5 μm. Opaque photoanodes were obtained following an analogous procedure, but employing a different commercial titania paste (Dyesol 18NR-AO); their final thickness was 6.5 μm. In both cases, the electrode active area was 0.25 cm$^2$. Counter electrodes (CE) were obtained by screen printing a commercial platinum-containing paste (Chimet) on pre-drilled conductive glass plates and by heating at 420 °C for 15 minutes. Titania photo-electrodes were sensitized by overnight immersion at rt into the appropriate dye solution (0.1mM in THF for dye TTZ3-5, 0.2 mM in EtOH for dye D5, 0.3 mM in EtOH for dye Z907), either in the absence or in the presence of 1 mM chenodeoxycholic acid (CDCA). After sensitization, the photoanodes were rinsed with THF or EtOH depending on the dye solvent, and then dried. A TiO$_2$-sensitized photoanode and a Pt counter electrode were assembled into a sealed sandwich-type cell using either a 25 μm or a 60 μm hot-melt Surlyn® gasket (Solaronix). A drop of the I$^-$/I$_3^-$ containing commercial HPE electrolyte solution (Dyesol) was placed on the drilled hole on the back of the counter electrode and was driven into the cell by vacuum backfilling. The hole was finally sealed by using additional sealing film and a small glass cover.

The devices underwent photovoltaic characterization by using a AM 1.5G solar simulator equipped with a Xenon lamp (KHS Solar Constant 1200). The measurements were performed with a power of incoming radiation of 100 mW/cm$^2$. J/V curves were obtained by applying an external bias to the cell and measuring the generated photocurrent with a Keithley model 2400 digital source-meter. A black shading mask was used to avoid overestimation of the measured parameters. IPCE spectra were measured with a special apparatus built using the following components: Newport model 70 612 Xenon lamp (150 W), Cornerstone 130 1/8 m monochromator and Keithley model 2400 digital source-meter.
