Chem. Commun.
**General consideration.** All reagents, including FeCl₃·6H₂O (Acros), Sodium oleate (TCI), oleic acid (Aldrich), 1-Octadecene (Aldrich), Igepal CO-520 (Aldrich), tetraethyl orthosilicate (Acros), NaBH₄ (Samchun chem.), H₂O₂ (Samchun chem.), ascorbic acid (Samchun chem.), NH₃BH₃ (Aldrich), N₂H₄·H₂O (Junsei), HAuCl₄·xH₂O (Strem), Na₂PdCl₄·3H₂O (Strem), Na₂PtCl₄·xH₂O (Strem), Ni(NO₃)₂·6H₂O (Strem), NiCl₂·6H₂O (Aldrich), CoCl₂·6H₂O (Kanto), 1-chloro-4-nitrobenzene (Aldrich), 1-bromo-4-nitrobenzene (Aldrich), 1-iodo-4-nitrobenzene (Aldrich), 4-nitroaniline (Aldrich), 4-nitrophenol (Aldrich), 4-nitroanisole (Aldrich), Ethyl 4-nitrobenzoate (Alfa Aesar), and 4-nitrostyrene (TCI), were used as purchased.

Transmission electron microscopy analyses (TEM) were conducted with JEOL JEM-2100 and JEM-ARM200F instruments. Samples were suspended in water by sonication and then dropped (20 μL) on a carbon-coated copper grid. X-ray diffraction patterns were obtained with an X-Ray Diffractometer (18kW, Rigaku, Japan). The metal contents were determined by inductively coupled plasma–atomic emission spectrometry (ICP–AES) using Direct Reading Echelle ICP (Leeman Labs, Inc., NH USA). ¹H NMR spectra were recorded with a Bruker Avance III (300 MHz, 600 MHz) FT-NMR spectrometer. The analysis of the field dependent magnetization property was performed by using a MPMS XL-7 superconducting quantum interference device (SQUID) magnetometer at 300 K and 5 K.

**Synthesis of less-noble Ni-based nanocrystals inside the cavity.**

**Control experiments for Ni growth inside a Au@h-SiO₂ cavity with various reducing agent.** Au@h-SiO₂ nanospheres were prepared through a previously reported procedure,¹⁰ which included the encapsulation of an Fe₃O₄/Au hybrid nanocrystal with a silica shell via a microemulsion technique and the selective etching of Fe₃O₄ from the silica nanosphere by reacting with NaBH₄. The resulting Au@h-SiO₂ used in this study had a 3.3 nm Au nanocrystal inside the cavity. For the Ni growth reaction, Au@h-SiO₂ nanospheres (2 mg) and NiCl₂ (10 mg) were mixed in distilled water (1 mL). Then, an aqueous solution containing 2.2 mmol of L-ascorbic acid, H₂O₂, N₂H₄·H₂O, or NaBH₄ (1 mL) was added to the suspension. The reaction was stirred gently at 45 °C with a magnetic stirrer. After 1.5 h, the resulting solids were collected by centrifugation and purified by three cycles of dispersion in an water and collection by centrifugation.
Preparation of the \((\text{Fe}_3\text{O}_4/\text{Au})@(\text{SiO}_2/\text{M}^{2+})\) \((\text{M} = \text{Pd, Ni})\) and \((\text{Fe}_3\text{O}_4/\text{AuPt}^{2+})@\text{SiO}_2\) nanospheres. \text{Fe}_3\text{O}_4 nanocrystals with an average core size of 10 nm were prepared through the previously reported procedure.\cite{S2} The \((\text{Fe}_3\text{O}_4/\text{Au})@(\text{SiO}_2/\text{M}^{2+})\) \((\text{M} = \text{Pd, Ni})\) and \((\text{Fe}_3\text{O}_4/\text{AuPt}^{2+})@\text{SiO}_2\) nanospheres were made by a modification of the previously reported reverse microemulsion technique.\cite{S1} Igepal CO-520 (0.6 mL) was dispersed by sonication in a round-bottom flask containing cyclohexane (10 mL). Next, \text{Fe}_3\text{O}_4 nanoparticles (3 mg) dispersed in cyclohexane were added. An aqueous solution of HAuCl\(_4\) (16 mg/mL, 0.05 mL) was added dropwise to the reaction mixture to form a transparent solution. Then, Na\(_2\)PdCl\(_4\), Ni(NO\(_3\))\(_2\), or Na\(_2\)PtCl\(_4\) aqueous solution (16 mg/mL, 0.05 mL) was introduced, followed by ammonium hydroxide solution (28–30%, 0.16 mL) with vigorous stirring. Finally, tetraethyl orthosilicate (TEOS, 0.2 mL) was added, and stirring was continued for 21 h. The resulting nanospheres were purified by repeating the redispersion in EtOH and water and then by centrifugation.

Control experiments excluding either TEOS or both HAuCl\(_4\) and TEOS during the silica encapsulation procedure. Igepal CO-520 (0.6 mL) was dispersed in a round-bottom flask containing cyclohexane (10 mL). Next, \text{Fe}_3\text{O}_4 (3 mg) nanoparticles dispersed in cyclohexane were added. An aqueous solution of HAuCl\(_4\) (16 mg/mL, 0.05 mL) was added dropwise to the reaction mixture to form a transparent solution (this step was omitted during the experiment excluding HAuCl\(_4\)). The subsequent introduction of Na\(_2\)PdCl\(_4\), Ni(NO\(_3\))\(_2\), or Na\(_2\)PtCl\(_4\) solution (16 mg/mL, 0.05 mL) was followed by the addition of ammonium hydroxide solution (28–30%, 0.16 mL) with vigorous stirring. The resulting nanospheres were purified by repeated cycles of dispersion in EtOH and water and followed by centrifugation.

Control experiments excluding HAuCl\(_4\) during the silica encapsulation procedure. Igepal CO-520 (0.6 mL) was dispersed in a round-bottom flask containing cyclohexane (10 mL). Next, \text{Fe}_3\text{O}_4 (3 mg) nanoparticles dispersed in cyclohexane were added. An aqueous solution of Na\(_2\)PdCl\(_4\), Ni(NO\(_3\))\(_2\), or Na\(_2\)PtCl\(_4\) solution (8 mg/mL, 0.1 mL) was added dropwise to the reaction mixture to form a transparent solution). Then, ammonium hydroxide solution (28–30%, 0.16 mL) was added with vigorous stirring. Finally, tetraethyl orthosilicate (TEOS, 0.2 mL) was added, and stirring was continued for 21 h. The resulting nanospheres were purified by repeating the redispersion in EtOH and water and then by centrifugation.

Sodium borohydride treatment of \text{Fe}_3\text{O}_4@\text{SiO}_2/\text{M}^{2+} \((\text{M} = \text{Pd, Ni, Pt})\). An aqueous solution of NaBH\(_4\) (0.2 M, 1 mL) was added to an aqueous suspension (2 mL) of
Fe₃O₄@SiO₂/M²⁺ (M = Pd, Ni, Pt) (3 mg) at 40 °C; the reactions were stirred for 1 h at a constant temperature. The brown color of the suspension changed to black with the evolution of H₂ gas. The resulting solids were collected by the centrifugation and purified by repeated dispersion in water followed by centrifugation.

Control experiments for preparation of the (Fe₃O₄/Au)@(SiO₂/M²⁺) (M = Pd, Ni) with various Pd²⁺ and Ni²⁺ contents. Aqueous stock solutions were prepared for Na₂PdCl₄ at 4, 8, 32 and 64 mg/mL and Ni(NO₃)₂ at 16 and 32 mg/mL. Igepal CO-520 (0.6 mL) was dispersed by sonication in a round-bottom flask containing cyclohexane (10 mL). Next, Fe₃O₄ nanoparticles (3 mg) dispersed in cyclohexane were added. An aqueous solution of HAuCl₄ (16 mg/mL, 0.05 mL) was added dropwise to form a transparent suspension. The desired Na₂PdCl₄ or Ni(NO₃)₂ stock solution (0.05 mL) was added, followed by ammonium hydroxide solution (28–30%, 0.16 mL) with vigorous stirring. Finally, TEOS (0.2 mL) was added, and stirring was continued for 21 h. The resulting nanospheres were purified by repeated cycles of dispersion in EtOH and water followed by centrifugation.

Reductive etching of Fe₃O₄ from (Fe₃O₄/Au)@(SiO₂/M²⁺) (M = Pd, Ni) and (Fe₃O₄/AuPt²⁺)@SiO₂. An aqueous solution of NaBH₄ (0.2 M, 1 mL) was added to an aqueous suspension (2 mL) of (Fe₃O₄/Au)@(SiO₂/M²⁺) (M = Pd, Ni) (3 mg) or (Fe₃O₄/AuPt²⁺)@SiO₂ (3 mg) at 40 °C; the reactions were stirred for 1 h at a constant temperature. The brown color of the suspension changed to black with the evolution of H₂ gas. The resulting solids were collected by the centrifugation and purified by repeated dispersion in water followed by centrifugation.

Growth of Ni nanoparticle inside (Au/Pd)@h-SiO₂ cavities. To form the Ni-hydrazine complex, NiCl₂ (50 mg, 0.2 mmol) was dissolved in deionized water (0.5 mL), and hydrazine (0.109 mL, 2.2 mmol) was added. Violet precipitates were formed immediately. The resulting solids were collected by centrifugation and purified twice by repeated dispersion in water. An aqueous solution of Ni-hydrazine complex (15 mg) and hydrazine (0.054 mL, 1.1 mmol) were prepared in distilled water (1.5 mL) in a capped vessel. The solution was degassed by sparging with N₂ for 30 min. (Au/Pd)@h-SiO₂ nanospheres (2 mg) dispersed in degassed water (0.5 mL) were transferred to the solution via syringe and stirred for 1.5 h at 45 °C in a closed vessel without ventilation. The color of the suspension slowly changed from violet, through light brown, to black with the evolution of H₂ gas. The Ni@SiO₂ was collected by placing a small magnet on the side wall of the reaction vessel and removing the supernatant
solution by using a syringe. The resulted Ni@SiO$_2$ were re-dispersed in a degassed water and stored as a suspension under the nitrogen environment.

**Growth of Ni/Co alloy nanoparticles inside (Au/Pd)@h-SiO$_2$ cavities.** An aqueous solution of Ni-hydrazine complex (10 mg) and hydrazine (0.054 mL, 1.1 mmol) were prepared in distilled water (1.5 mL) in a capped vessel. The solution was degassed by sparging with N$_2$ for 30 min. (Au/Pd)@h-SiO$_2$ nanospheres (2 mg) dispersed in degassed water (0.5 mL) were transferred to the solution via syringe and stirred for 20 min at 45 °C in a closed vessel. Then, the aqueous solution of CoCl$_2$ (0.42 M, 0.075 mL) was added and the solution was maintained for 40 min at 45 °C in a closed vessel. The resulting solids were collected by the centrifugation and purified by repeated dispersion in water followed by centrifugation.

**Control experiment for Co growth inside (Au/Pd)@h-SiO$_2$ cavities.** (Au/Pd)@h-SiO$_2$ nanoparticles (2 mg) and hydrazine (1.1 mmol) were suspended in water (2 mL). Aqueous CoCl$_2$ (0.42 M, 0.075 mL) was added to the suspension and stirred at 45 °C for 1 h in the closed vessel. The resulting solid was collected by centrifugation and washed with water three times.

**Evaluation of catalytic effectiveness of the Ni@SiO$_2$.**

**Hydrolytic dehydrogenation of NH$_3$BH$_3$.** A one-necked Schlenk flask containing a stir bar was placed on a magnetic stirrer. A burette filled with water was connected to a reaction flask to measure the volume of hydrogen gas evolved from the reaction. The other end of the burette was connected to a pressure-equalization funnel. The Ni@SiO$_2$ (0.064, 0.053, 0.043, and 0.032 mM, based on Ni content) in water (1.5 mL) was introduced into the flask. Then, aqueous NH$_3$BH$_3$ solution (0.5 mL, 30.8 mg, 1 mmol) was added into the reaction flask to initiate the reaction. The evolution of gas was monitored using the gas burette. The reactions were carried out at room temperature under ambient atmosphere. Recycling experiments were carried out by additionally injecting a aliquot of the NH$_3$BH$_3$ solution (0.5 mL, 1 mmol) to the flask after each run.

**Catalytic hydrogenation of nitroarene compounds.** Nitroarenes (0.1 mmol), hydrazine (4 mmol, 0.2 mL), and H$_2$O (0.8 mL) were mixed in reaction tube, and then the Ni@SiO$_2$ catalyst (15 mol%) was added to the solution. The mixture was stirred until nitroarenes was completely consumed at room temperature, as determined by TLC (0.25 mm E. Merck silica gel plates (60F-254), with UV light detection). After completion, the reaction mixture was
extracted with ethyl acetate (3 × 1 mL) and filtered to remove the catalysts. The combined organic layers were evaporated at reduced pressure. The products were identified by 1H NMR. For investigating the recylability of the Ni@SiO₂ catalyst, the catalyst was collected after the reaction by placing a small magnet on the side wall of the reaction vessel and decanting the product solution, which was followed by the succesive washing with 1 ml of distilled water and 1 ml of actone. The consecutive run was performed by adding the reactants solution to the reaction vessel containing the recovered Ni@SiO₂ catalyst.
