1.1 Techniques for the identification of compounds

\(^1\)H and \(^{13}\)C-NMR spectra were recorded on a Varian 400-MR spectrometer working at 400 MHz for \(^1\)H or 100.6 MHz for \(^{13}\)C. All NMR data were obtained in CDCl\(_3\). Chemical shifts are reported in parts per million (ppm, \(\delta\)) and are referenced to the residual signal of the solvent. Coupling constants are reported in Hertz (Hz). Spectral splitting patterns are designated as s (singlet), d (doublet), t (triplet), q (quartet), m (complex multiplet).

HPLC-MS analysis was carried out in an Agilent 1260 infinity Series chromatograph equipped with photodiode array detector (200–600 nm) and coupled to an Agilent 6130 quadrupole LC/MS. Separation was achieved using a Discovery® C18 (15m x 4.6 mm, 5µm particle size) column and an ACN:MeOH 85:15 mixture at 1.0 mL/min flow rate. The DAD detector was set at 400 nm matching the Soret band of porphycenes. API-ES positive ionization mode at 80V cone voltage was used. Fragmentations were scanned from 500 to 2500 m/z. Peaks were identified by their characteristic MS fragmentations.

1.2 Techniques for the characterisation of nanostructures

The size and morphology of tetraethylenglycol alkyl-thiol stabilized gold nanoclusters were determined by means of transmission electron microscopy (TEM). For TEM examination a single drop (15 µL) of the EtOH solution of the nanostructures was placed onto a copper grid coated with a carbon film. The grid was left to dry in air at room temperature. TEM analysis were carried out in a JEOL 2010F microscope, working at 200 kV. The particle size distribution was evaluated from several micrographs by means of an automatic image analyser software.

1.3 Spectroscopic techniques

The photophysical properties of porphycene derivatives were measured in spectroscopic grade acetone.

Absorption spectra were recorded on a Varian Cary 6000i dual-beam UV/Vis spectrophotometer. Fluorescence emission spectra were recorded on a Jobin Yvon-Spex Fluoromax-4 spectrofluorometer. Fluorescence quantum yields (\(\Phi_F\)) were determined by comparison of the area under the emission curves for solutions of 9-ITPP0 and 9-amide porphycene derivatives in acetone with TPP in toluene (\(\Phi_F=0.11\))\(^1\) or ATAZPos and TAZPos in acetone with ICG in DMSO (\(\Phi_F=0.12\))\(^2\) respectively. The absorbance of both sample and reference solutions were below 0.05 in order to prevent inner filter effects and matched at the excitation wavelength. Emission intensities were corrected for the refractive index of the solvent.
Fluorescence decays were recorded with a time-correlated single photon counting system (Fluotime200, PicoQuant GmbH, Berlin, Germany) equipped with a red sensitive photomultiplier. Excitation was achieved by means of a 375 nm picosecond diode laser working at 10 MHz repetition rate and the photon counting frequency was kept below 1%. Fluorescence lifetimes were determined using PicoQuant FluoFit 4.6 data analysis software.

The specific ¹⁰² near-infrared phosphorescence kinetics were detected by means of a customized PicoQuant Fluotime 200 system described in detail elsewhere.¹ The time-resolved emission signals were fitted by Eq. (1):

\[
S_t = S_0 \times \frac{\tau_\Lambda}{\tau_\Lambda - \tau_T} \left( e^{-t/\tau_\Lambda} - e^{-t/\tau_T} \right)
\]

where \(S_0\) is proportional to \(\Phi_\Lambda\), \(\tau_\Lambda\) is the ¹⁰² lifetime and \(\tau_T\) is the lifetime of the photosensitizer’s triplet state. The \(\Phi_\Lambda\) values were determined by comparing \(S_0\) for 9-ITPPo, ATAZPos and TAZPos and a reference photosensitize, TPP (\(\Phi_\Lambda=0,63\)).²

Triplet lifetimes of the argon fluxed samples were monitored with a home-built nanosecond flash photolysis setup using a Q-switched Nd:YAG laser (Surelite I-10, Continuum) for excitation at 355 nm and a Xe lamp (PTI, 75 W) for probing the transient absorption with right-angle geometry. The analysing beam passed through a dual grating monochromator (mod. 101, PTI) and was detected by a Hamamatsu R928 photomultiplier. The signal was fed to a Lecroy WaveSurfer 454 oscilloscope for digitizing and averaging (typically 10 shots) and finally transferred to a PC computer for data storage and analysis. Kinetic analysis of the individual transients decays afforded the values of \(\tau_T\).

1.4 Computational methods

Geometry optimizations of ground states were performed using the DFT method with B3LYP functional at 6-31G(d) level of theory. Gaussian 09 software was used for all calculations⁵.
2. Experimental section

9-amino-2,7,12,17-tetraphenylporphycene (9-ATPpo) was prepared in agreement with previously described synthetic procedures. This compound was used as starting reagent for the synthesis of the novel porphycene derivatives described below (Scheme S1).

Scheme S1: General synthetic scheme for the preparation of thiazolo[4,5-c]porphycenes

2.1. Synthesis of 9-isothiocyanate-2,7,12,17-tetraphenylporphycene

To a solution of 9-ATPpo (50 mg, 7.5.10⁻² mmol) in CH₂Cl₂ (10 mL) was added 1,1'-thiocarbonyldi-2(1H)-pyridone (53 mg, 3 eq, 0.23 mmol). The mixture was stirred 16h at room temperature. The solvent was evaporated and the mixture was purified by chromatography with silica column eluting with CH₂Cl₂. The product was then crystallized, by dissolving it in toluene (5 mL) and pouring it in acetonitrile (50 mL), to provide a green product (38 mg, 5.6.10⁻² mmol, 75 %). ¹H NMR (400 MHz, CDCl₃) δ 9.70 – 9.61 (ABq, 2H, J_AB = 11.1 Hz), 9.55 (s, 1H), 9.43 (s, 1H), 9.39 (s, 2H), 9.30 (s, 1H), 8.29 – 8.19 (m, 6H), 8.08 – 8.00 (m, 2H), 7.88 – 7.59 (m, 12H), 3.77 (s, 1H), 3.29 (s, 1H). ¹³C NMR (100 MHz, CDCl₃) δ 145.47, 145.15, 144.79, 143.64, 143.08, 142.96, 139.93, 138.03, 137.42, 136.14, 135.75, 135.18, 134.83, 134.03, 133.52, 131.54, 131.51, 131.48, 130.91, 129.47, 129.29, 129.26, 128.73, 128.41, 128.22, 127.94, 127.30, 124.14, 124.07, 118.27, 115.57, 115.16, 114.83. 2.5 Synthesis of tetraethylenglycol alkyl-thiol stabilized gold nanoclusters

This synthesis was adapted from previously described synthesis of tri- and hexaethylenglycol alkyl-thiol stabilized gold nanoclusters with some modifications. Briefly, 30 mg of 23-mercapto-3,6,9,12-tetraoxatricosan-1-ol (90 μmol) and 3.3 mg of 1-amino-3,6,9,12-tetraoxatricosane-23-thiol (10 μmol) were mixed with 10 mg of tetrachloroauric acid trihydrate (30 μmol) in 7.0 mL of MeOH. 0.6 mL of a freshly prepared solution of NaBH₄ (1.3 M) was added at an input speed of 4.8 mL/h under stirring. The mixture was stirred at room temperature during 2.5 h and then the solvent was removed under reduced pressure. Next, the remaining crude was dispersed in 15 mL of a 2:1 water:ethanol mixture and purified by dialysis twice (10h, 900 mL). The aqueous solution was basified using a 0.1 M solution of KOH and extracted.
several times with CHCl₃. The organic layers were dried over anhydrous Na₂SO₄ and the solvent was removed under reduced pressure. Finally, the brownish solid powder was suspended in 20 mL of absolute EtOH.

2.6 Labelling procedure of gold nanoclusters

100 μL of 9-ITPPo (100 μM) in toluene were gently added to 2 mL of AuNCs (2.9 μM) in ethanol. The mixture was stirred at room temperature for 24 h and several absorption spectra were recorded at different times (Figure S30). After the reaction completion, the solvent removed under reduced pressure. Next, the greenish powder was redispersed in water and purified by successive water dialysis.

![Figure S30: Time evolution of the absorption spectra of 9-ITPPo upon binding to AuNCs.](image)

2.7 Labelling procedure of bovine serum albumin

20 μL of 9-ITPPo (16 mM) were added to a stirred solution of bovine serum albumin (BSA, 5 mg, 0.08 μmol) in a sodium bicarbonate/sodium carbonate buffer (250 mL, pH 9.4). The reaction vessel was protected from light and stirred for 36 h at room temperature. The bioconjugate was purified using the acetone precipitation method previously reported by Hamblin et al. Briefly, the crude bioconjugate preparations were diluted with 1.5 mL of bicarbonate/carbonate buffer and 20 mL of acetone at 4 °C were slowly added. After 5 h, the green suspension was centrifuged at 4000g and washed several times with acetone until colourless supernatant. Then, the pellet was redissolved in 20 mL of PBS and exhaustively dialyzed against 1 L of PBS for 3 days in order to remove all traces of acetone.
3. Additional results

3.1 TEM examination of AuNCs

For size determination, a single drop (15 μL) of the EtOH solution of the gold nanoclusters was placed onto a copper grid coated with a carbon film. The grid was left to dry in air at room temperature. TEM analysis was carried out in a JEOL 2010F microscope working at 200 kV. The particle size distribution of the gold nanoclusters was evaluated from several micrographs by means of an automatic image analyser software (Figure S31).

3.4 Optical properties of 9-benzamido porphycene and 2-phenylthiazolo[4,5-c] 2,7,12,17-tetraphenylporphycene.

Similarly to ATAZPos, both the absorption and emission spectra of TAZPo is red shifted with respect to its corresponding 9-AmPo precursor (Figure S36 and Table S1). The most relevant property of this new porphycene derivative is an unprecedented 2-fold enhancement of its photosensitising properties which makes it an even better candidate for photodynamic therapy.
