**S(a) – Experimental Section**

**Sample preparation.** The cyanine dye DMSB was synthesized according to Hamer\(^1\) and Brooker's\(^2\) methods, and the purity was evaluated by mass spectrometry and nuclear magnetic resonance (NMR) [SI, S(a) part]. All oligonucleotides were purchased from Sangon Biotech Co., Ltd. (Shanghai, China) and purified by HPLC (purity 98%). \(CT\) was directly purchased from Sigma Aldrich Inc. (cat# D4522). Analytical grade methanol, KCl, \(\text{KH}_2\text{PO}_4\) and \(\text{K}_2\text{HPO}_4\) were purchased from Beijing Chem. Co. (China). Ultrapure water prepared by Milli-Q Gradient ultrapure water system (Millipore) was used throughout the experiments. The stock solution of DMSB is prepared by dissolving it in methanol to 2 mM and then storing in dark at 4 °C. The stock solutions of \(\text{TBA}\) was prepared by dissolving them directly into phosphate buffer solution (PBS, 20 mM \(\text{KH}_2\text{PO}_4/\text{K}_2\text{HPO}_4\), 100 mM KCl, pH 7.4), filtered by a microfiltration membrane (Φ = 0.22 μm) and then heated to 90 °C for 5 min and then gradually cooled to room temperature at a rate of 1 °C·min\(^{-1}\) to form secondary structures. Concentrations of \(\text{TBA}\) stock solutions were determined by their absorbance at 260 nm. All DNA samples were stored at 4 °C. The measured samples were prepared by adding different amount of \(\text{TBA}\) stock solution into 1mL PBS containing 12 μM DMSB. Then the samples were incubated 2h in darkness at 4 °C before subjected to measurement.

**UV-vis and fluorescence spectroscopic measurements.** The UV-vis absorption spectra were measured by an Agilent-8453 UV/visible spectrophotometer equipped with a Peltier effect cuvette holder in 10 mm quartz cells at 4 °C. Fluorescence spectra were taken on a Hitachi F-4500 spectrophotometer in a 10 mm quartz cell at room temperature. Xenon arc lamp was used in the excitation light source in fluorescence measurement. The excitation wavelength was 520 nm. Both excitation and emission

---

slits were 5 nm and the voltage was 400 V with a scan speed of 240 nm min⁻¹.

**Circular dichroism (CD) spectra measurements.** All the CD spectra were recorded on a JASCO J-815 spectrophotometer in a 10 mm path-length quartz cell at 4 °C. All spectra were collected with scan speed of 200 nm min⁻¹ and a response time of 0.5 s between 700 and 400 nm with 5 scans averaged.

**NMR Experiments.** The stock solution of DMSB for NMR experiments was prepared by dissolving 22.2 mg DMSB into 1 mL DMSO-d6 (40 mM). The stock solution of *TBA* was prepared by dissolving it directly into 0.5 mL NMR buffer solution [20 mM KH₂PO₄/K₂HPO₄, 100 mM KCl, 90% H₂O/10% D₂O (v/v), pH = 7.4] and then dialyzed through a bag with cut-off molecular weight of 500 for 12 hours for desalting purpose. The measured sample for ¹H-NMR titration as well as NOESY was prepared by adding different amount of DMSB stock solution to NMR buffer containing 0.5 mM *TBA*. All NMR spectra were recorded on a Bruker Avance 600 MHz spectrometer which is equipped with a 5mm BBI probe capable of delivering z-field gradients up to 50 G cm⁻¹. 1D chemical shifts were referenced relative to 3-(trimethylsilyl)-propanoic acid (TSP). The 1D spectra were recorded by the standard Bruker pulse program p3919gp that applies 3-9-19 pulses with gradients for water suppression. All the experiments were acquired 128 scans for each spectrum with a relaxation delay of 2 s at 303 K.

**Partial charge calculation and assignment.** The three dimensional crystal structure of TBA was obtained from the Brook Haven Protein Data Bank (PDB ID: 1QDF). The partial charges and structure of DMSB was calculated and optimized by Gaussian 03 using DFT method with an HF/6-311++G(d, p) basis set at the B3LYP level with water as the solvent. While the partial charges of the bases on TBA were automatically assigned by the CHARMm forcefield. Then the structures of DMSB

---

and TBA were subjected to surface calculation. The wire-mesh style electrostatic surfaces were calculated by using Discovery Studio 3.5 with the interpolated method (Accelrys, San Diego, CA).
S(b) – Identification of cyanine dye DMSB

The structure and purification of cyanine dye DMSB were identified by MS-ESI, NMR and absorption spectroscopy.

![Figure S1. The numbering scheme of molecular structure of DMSB](image1)

a) MS-ESI

From the mass spectrum, the measured molecular weight of DMSB is 475.1, which is consistent with the calculated value, 475.5.

c) UV-vis spectrum research and absorption coefficient calculation

Figure S4. The absorption spectra of DMSB monomer in methanol. Inset gives the curve of the absorbance at 554 nm against the concentration of DMSB. Based on lambert-beer's law, the molar absorption coefficient of DMSB monomer is:

$$e_{\text{1cm,554nm}}^{\mu} = 1.083 \times 10^3 \text{ M}^{-1} \cdot \text{cm}^{-1}.$$
**Figure S5.** The absorption spectra of 12 μM DMSB in methanol (black), phosphate buffer solution (PBS, 20 mM K$_2$HPO$_4$/KH$_2$PO$_4$, 100 mM KCl, pH = 7.4) (blue) and PBS in the presence of 0.6 μM TBA (red).
