Materials and Methods

Materials

Gold foil (thickness 0.1 mm, 99.99%), gold wire (diam. 0.25 mm, 99.9%), gold(III) chloride trihydrate (≥99.9%), sodium borohydride (≥98.0%), cetyltrimethylammonium chloride (≥99.5%), L-ascorbic acid (≥99.0%), potassium hydroxide (99.9%), Pt gauze (99.9%), Pt wire (99.9%), Na₂CO₃ (99.999%, TraceSELECT®), and H₂SO₄ (≥95%, TraceSELECT®) were purchased from Sigma-Aldrich; gold disk (thickness 4 mm, diam. 5 mm, 99.99%) was purchased from Pine Research Instrumentation Inc.; oxygen (99.99%), and carbon dioxide (99.99%) was purchased from Praxair. Gold foil and wire were etched in fresh aqua regia for ~20 s, and then rinsed with deionized water thoroughly prior to experiments. All other chemicals were used without further purification. Electrolyte solutions were prepared with deionized water (Ricca Chemical, ASTM Type I). NaHCO₃ solution was prepared by vigorously bubbling CO₂ gas through Na₂CO₃ solutions.

Preparation of OD-Au on Gold Foil and Gold Disk

A piece of gold foil (~0.5 cm²) was immersed in aqueous 0.5 M H₂SO₄ solution in an one-compartment electrochemical cell with a platinum gauze auxiliary electrode and a Hg/Hg₂SO₄ reference electrode (0.50 M H₂SO₄, CH Instruments). Symmetric 1 kHz square-wave pulses between 2.70 V and 0.70 V were applied for 5 min (300,000 cycles) with the use of a Gamry Reference 600 Potentiostat. After pulsed anodization, the foil was rinsed very gently with deionized water to remove remaining H₂SO₄ from the as-grown oxide layer. Then the foil was immersed in CO₂-saturated NaHCO₃ solution and held at −1.03 V vs Ag/AgCl reference electrode (3.0 M KCl, World Precision Instruments) for 5 min to fully reduce the gold oxide layer. The preparation of OD-Au on Au disk was the same as above except that a gold disk was used.

Syntheses of Shaped Au Nanoparticles (NPs)

The procedure was adapted from a two-step, seed-mediated method established in literature (refs 8 and 9 in the main text). The Au seed solution was prepared by injecting 0.45 mL of 0.02 M freshly prepared, ice-cooled NaBH₄ solution into 10 mL solution containing 0.25 mM HAuCl₄ and 0.1 M cetyltrimethylammonium chloride (CTAC) while stirring. The resulting solution was left undisturbed for 2 h to allow complete decomposition of excess NaBH₄.

Growth solution I and growth solution II were prepared with a different recipe for each type of polyhedral nanoparticles. Growth solution I was prepared by adding 0.01 mL of 0.01 M NaBr and 0.09 mL of 0.04 M ascorbic acid (cubes), or 0.01 mL of 0.01 M NaBr and 0.15 mL of 0.04 M ascorbic acid (dodecahedra), or 0.01 mL of 0.001 M KI and 0.22 mL of 0.04 M ascorbic acid (octahedra) into 10 mL of 0.25 mM HAuCl₄ and 0.1 M cetyltrimethylammonium chloride (CTAC) while stirring. The resulting solution was left undisturbed for 2 h to allow complete decomposition of excess NaBH₄.

Growth solution II was prepared with the same concentration as growth solution I but 20-fold higher volume. 0.025 mL Au seed solution was injected into the growth solution I while stirring. After ~20 s, 0.5 mL of the resulting pink solution from growth solution I was injected into growth solution II. After stirring for 1 min, the solution was left undisturbed for 2 h for growth. The nanoparticles were centrifuged and washed repeatedly with DI water. After washing, the nanoparticles were re-dispersed to ~ 2 mg/mL in DI water for electrode preparation experiments.
Electrochemical Measurements

A CH Instruments 760D Potentiostat or a Gamry Reference 600 Potentiostat was used for all oxygen reduction experiments. Experiments were performed at room temperature (20 °C). A piece of platinum gauze was used as the auxiliary electrode. All potentials were measured against an Hg/Hg$_2$Cl$_2$ reference electrode (satu. KCl, CH Instruments) or Ag/AgCl reference electrode (3.0 M KCl) and converted to the RHE reference scale using $E$ (vs RHE) = $E$ (vs Hg/Hg$_2$Cl$_2$) + 0.241 V + 0.0591 V × pH or $E$ (vs RHE) = $E$ (vs Ag/AgCl) + 0.21 V + 0.0591 V × pH.

For shaped Au NPs, the suspension was mixed with ~10 wt.% Nafion and 0.020 mL of the catalyst ink was drop-dried onto the glassy-carbon rotating disk electrode for electrochemical experiments.

Electrochemical Surface Area (ECSA) Measurement

The electrochemical surface area of the ODAu and shaped Au nanoparticle electrodes were determined by measuring the desorption charge associated with the stripping of the underpotential deposited Cu monolayer on Au (Figure S2). The experiments were conducted in 0.50 M H$_2$SO$_4$ solution with a piece of Pt gauze as the counter electrode and an Hg/Hg$_2$Cl$_2$ electrode (0.50 M H$_2$SO$_4$, CH Instruments) as the reference electrode. The desorption peaks at ~−0.1 V were integrated.

Pb-underpotential deposition (Pb-upd) Measurement

The Pb-upd measurements of ODAu and shaped Au nanoparticles were conducted in 0.1 M NaOH solution containing 1 mM Pb(OAc)$_2$ with a piece of Pt gauze as the counter electrode and an Ag/AgCl electrode (3.0 M KCl, World Precision Instruments) as the reference electrode. The scan rate was 50 mV/s.

Koutecky-Levich Kinetics and Determination of $n$ Values

Koutecky-Levich Equation: $j^1 = j_k^{-1} + j_d^{-1}$

$\dot{j}_d = 0.62nFD_0^{2/3}v^{-1/6}C_0^{1/2}$, diffusion-limited current density, A·cm$^{-2}$

$F$: Faraday’s Constant, 96485 C·mol$^{-1}$

$D_0$: diffusion coefficient of O$_2$ in 0.1 M KOH (1.93×10$^{-5}$ cm$^2$·s$^{-1}$)$^{[1][2]}$

$v$: kinematic viscosity of the electrolyte, 0.1 M KOH, (1.09×10$^{-2}$ cm$^2$·s$^{-1}$)$^{[1][2]}$

$C_0$: saturation concentration of O$_2$ in 0.1 M KOH at 1 atm O$_2$ pressure, (1.26×10$^{-6}$ mol·cm$^{-3}$)$^{[1][2]}$

$\omega$: rotation rate, rad·s$^{-1}$

0.62$FD_0^{2/3}v^{-1/6}C_0$ = 1.152×10$^{-4}$ A·cm$^{-2}$·s$^{1/2}$·rad$^{-1/2}$

Taking 0.8 V as an example, the linear fitting of the plot of $j^{-1}$ vs $\omega^{-1/2}$ has a slope of 2195 A$^{-1}$·cm$^{-2}$·s$^{-1/2}$·rad$^{-1/2}$, which corresponds to $n = 3.95$.

Calculations of $n$ in the literature often use the $B$ factor, which is the slope of the $i^{-1}$ vs $\omega^{-1/2}$ plot when $i$ is the current in units of mA and $\omega$ is the rotation rate in units of rpm. In this treatment, $B = 0.62nFD_0^{2/3}v^{-1/6}C_0S_{geo}(2\pi/60)^{1/2}$, where $S_{geo} = 0.196$ cm$^2$ is the geometric area of the electrode used in our experiments. For a 4e$^-$ reduction of O$_2$ in 0.1 M KOH with these electrodes, the theoretical value of $B = 2.92 \times 10^{-2}$ mA·rpm$^{-0.5}$. Taking 0.8 V as an example, the linear fitting of the plot of $i^{-1}$ vs $\omega^{-1/2}$ gives a slope of 3.46×10$^{-4}$ A$^{-1}$·rpm$^{-0.5}$, therefore, the experimental value of $B$ is 2.89×10$^{-2}$ mA·rpm$^{-0.5}$, which corresponds to $n = 3.96$.
