Experimental section

General procedures: All operations were carried out under a pure argon atmosphere using standard Schlenk techniques. All reagents were purchased from commercial sources and used without further purification. All other chemical reagents of analytical grade were used directly without further purification.

The $^1$H NMR and $^{13}$C NMR spectra were recorded on a Bruker DRX-400 at 298 K using deuterated solvents. Chemical shifts are given in ppm, and are referenced against internal TMS. High resolution mass spectrometric data were determined using an Agilent LTQ Orbitrap XL mass spectrometer. Fluorescence spectra were determined using a FluoroMax-4 spectrofluorometer (HORIBA) with a 5 nm slit for both excitation and emission. Lifetime was acquired through a time-correlated single photon counting (TCSPC) technique by using a HORIBA Jobin Yvon Fluorolog-3 modular spectrofluorometer. Absorption spectra were recorded using a Shimadzu UV-3100 spectrophotometer. All pH measurements of media were accomplished using a Model PHS-3C meter. Flow counters (HORIBA, STEC. SEC-E40JS. 60 SCCM) were used to control the oxygen concentration during the spectra. Confocal luminescence images were captured in the confocal laser scanning microscopy (CLSM, Zeiss LSM-710 microscope, Germany). The PLIM setup is integrated with Olympus FV1000 laser scanning confocal microscope. The lifetime values were calculated with professional software provided by PicoQuant Company.
Synthetic procedures

Synthesis and characterization of L1: 4-Ethynylphenol was prepared according to the reported procedure.[1] In a pressure tube were added 5-bromo-1,10-phenanthroline (300 mg, 1.16 mmol), 4-ethynylphenol (274 mg, 2.32 mmol), Pd(PPh₃)₄ (134 mg, 0.12 mmol), and n-propylamine (25 mL). After heating at 80 °C for 2 days, the reaction mixture was concentrated under reduced pressure. Chromatography on silica and recrystallization from methanol afforded L1 as an off-white solid (C₂₀H₁₂N₂O, 192 mg, 56%). ¹H NMR (400 MHz, DMSO-d₆): δ 10.07 (s, 1H), 9.22 (dd, J = 4.3, 1.7 Hz, 1H), 9.11 (dd, J = 4.3, 1.7 Hz, 1H), 8.84 (dd, J = 8.2, 1.7 Hz, 1H), 8.50 (dd, J = 8.2, 1.6 Hz, 1H), 8.31 (s, 1H), 7.91 (dd, J = 8.2, 4.3 Hz, 1H), 7.80 (dd, J = 8.1, 4.3 Hz, 1H), 7.60 (dd, J = 8.6 Hz, 2H), 6.89 (d, J = 8.7 Hz, 2H). ¹³C NMR (101 MHz, DMSO-d₆): δ 158.60, 150.58, 150.41, 145.34, 145.21, 136.06, 134.29, 133.43, 130.21, 127.96, 127.58, 123.86, 123.77, 119.22, 115.88, 111.87, 96.01, 84.01.

Synthesis of Ir₂(iqbt)₄Cl₂: 1-(Benzo[b]thiophen-2-yl) isoquinoline (Hiqbt) was prepared following a literature protocol.[2] Iridium dimer was synthesized according to the method by Nonoyama.[3] IrCl₃ (191 mg, 0.64 mmol) and Hiqbt (364 mg, 1.39 mmol) were heated for 24 h at 120 °C in a 3:1 mixture of 2-ethoxlyethanol (12 mL) and water (4 mL). A dark-brown suspension was formed. After cooling to room temperature, water (20 mL) was added and the suspension was filtered. The solid was thoroughly washed with water, diethyl ether and hexane. After that, the solid was dried under high vacuum to yield Ir₂(iqbt)₂Cl₂, which was used in the next step without further purification.

Synthesis and characterization of Ir-1: Under argon atmosphere, a mixture of Ir₂(iqbt)₂Cl₂ (154 mg, 0.1 mmol) and L1 (59 mg, 0.2 mmol) in CH₂Cl₂/CH₃OH (12 mL, 2:1, v/v) was heated to reflux for 6 h. After the completion of the reaction, the mixture was cooled to room temperature, and 10-fold excess of NH₄PF₆ was added. The suspension was stirred for 15 min and then filtered.
to remove the insoluble inorganic salts. The solution was concentrated to dryness under reduced pressure. The obtained solid was further purified by column chromatography on silica gel to yield \textbf{Ir-1} as a crimson solid (175 mg, 76%). ¹H NMR (400 MHz, CD$_3$CN-$d_3$) \(\delta\) 9.08 (d, \(J=8.4\), 3H), 8.60 (d, \(J=8.4\), 1H), 8.40 (s, 1H), 8.35 (dd, \(J=5.1, 1.4\), 1H), 8.27 (dd, \(J=5.1, 1.4\), 1H), 7.91-7.95 (m, 6H), 7.89-7.82 (m, 3H), 7.77 (dd, \(J=8.3, 5.1\), 1H), 7.60 (d, \(J=8.7\), 2H), 7.50 (s, 1H), 7.38 (d, \(J=6.6\), 1H), 7.34 (d, \(J=6.6\), 1H), 7.26 – 7.13 (m, 4H), 6.91 (d, \(J=8.8\), 2H), 6.73 (t, \(J=7.7\), 2H), 6.19 (d, \(J=8.3\), 2H). ¹³C NMR (101 MHz, CD$_3$CN-$d_3$) \(\delta\) 166.14, 159.58, 155.75, 155.55, 153.25, 152.93, 147.59, 146.99, 145.41, 144.46, 143.10, 139.69, 138.82, 138.22, 137.21, 137.17, 134.84, 133.66, 132.30, 132.16, 131.77, 130.30, 128.72, 128.66, 127.77, 127.43, 126.74, 125.89, 125.54, 123.57, 120.89, 116.88, 113.60, 99.58, 83.43. HR-MS (C$_{54}$H$_{32}$F$_6$IrN$_4$OPS$_2$, positive mode, \(m/z\)): Calcd. 1009.1647, found 1009.1646 for [(M-PF$_6$)].

\textbf{Synthesis and characterization of Ir-2:} 5-(Phenylethynyl)-1,10-phenanthroline (L2) was synthesized as described in the literature.⁴ The complex was prepared in a manner similar to that for \textbf{Ir-1}, with L2 instead of L1 (crimson solid, 62%). ¹H NMR (400 MHz, CD$_3$CN-$d_3$) \(\delta\) 9.07 (d, \(J=8.4\) Hz, 3H), 8.57 (dd, \(J=8.3, 1.4\) Hz, 1H), 8.43 (s, 1H), 8.33 (dd, \(J=5.0, 1.4\) Hz, 1H), 8.27 (dd, \(J=5.1, 1.4\) Hz, 1H), 7.96 – 7.87 (m, 6H), 7.87 – 7.79 (m, 3H), 7.78 – 7.64 (m, 3H), 7.49 (d, \(J=6.9\) Hz, 3H), 7.36 (dd, \(J=10.5, 6.6\) Hz, 2H), 7.22 – 7.10 (m, 4H), 6.70 (t, \(J=7.6\) Hz, 2H), 6.20 (d, \(J=8.2\) Hz, 2H). ¹³C NMR (101 MHz, CD$_3$CN-$d_3$) \(\delta\) 166.17, 155.73, 155.55, 153.34, 153.21, 147.60, 147.21, 145.45, 144.50, 143.16, 139.87, 138.78, 138.27, 137.24, 133.71, 132.98, 132.62, 132.30, 132.07, 130.97, 130.35, 129.94, 128.81, 128.72, 127.80, 127.47, 126.78, 125.93, 125.59, 123.60, 123.05, 122.57, 120.95, 98.79, 84.74. HR-MS (C$_{54}$H$_{32}$F$_6$IrN$_4$OPS$_2$, positive mode, \(m/z\)): Calcd. 993.1698, found 993.1691 for [(M-PF$_6$)].
Quantum yield determination

Phosphorescence quantum yields of \textbf{Ir-1} and \textbf{Ir-2} were determined in pure acetonitrile with Ru(bpy)$_3$Cl$_2$ ($\Phi$=0.018, $\lambda$=450 nm, air-saturated) as a reference. The quantum yield was calculated using the following equation:

$$\Phi_S = \Phi_R \frac{F_S A_S n_S^2}{F_R A_R n_R^2}$$

Where $\Phi_S$ and $\Phi_R$ are the photoluminescence quantum yield of the sample and that of the reference. $F_S$ and $F_R$ are the corresponding integrated fluorescence intensity (areas) of sample and reference spectra, respectively. $A_S$ and $A_R$ are the absorbance of the sample and reference solution at the reference excitation wavelength. $n_S$ and $n_R$ are the solvent refractive indexes of the sample and reference. Absorbance of sample and reference at their respective excitation wavelength was controlled to be lower than 0.05.

Cell lines and culture conditions

MCF-7 cells were cultured in RPMI (Roswell Park Memorial Institute)-1640 medium supplemented with 10% FBS (fetal bovine serum) in an atmosphere of 5% CO$_2$ and 95% air at 37 °C. In each experiment, cells treated with vehicle control (1% DMSO) were kept as the reference group.

Dark cytotoxicity assay

The \textit{in vitro} dark cytotoxicity of \textbf{Ir-1} towards MCF-7 cell lines was determined by MTT (3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide) assay. Cells were seeded into a 96-well cell culture plate at 1×10$^4$ per well, under 100% humidity, and were cultured at 37 °C with 5% CO$_2$ for 24h. \textbf{Ir-1} in different concentrations (1, 2, 4, 6, 8, 10, 20 μM diluted in RPMI-1640 medium) were added into the wells. The cells were subsequently incubated for 24h at 37 °C under 5% CO$_2$. After that, MTT (50 μL/well, 5 mg/mL) was added to each well and the plate was incubated for an additional 4 h at 37 °C under 5% CO$_2$. The medium was then replaced with 200 μL DMSO per well, and OD570 was monitored by an enzyme-linked immunosorbent assay reader (Thermo Scientific, Varioskan Flash).
Photo-cytotoxicity test
MCF-7 cells were used to determine the photo-cytotoxicity of Ir-1. After 4 h incubation with Ir-1 (1, 2, 4, 6, 8, 10, 20 μM diluted in RPMI-1640 medium), the cells were exposed to a 450 nm laser irradiation for 300 s (diode laser, Lasever, 30 J•cm\(^{-2}\)). After the irradiation, the cells were incubated for an additional 20 h at 37 °C under 5% CO\(_2\). MTT assay was conducted to measure the cell cytotoxicity.

Annexin V-PE apoptosis assay
The assay was performed according to the manufacturer’s (KeyGEN, China) protocol. MCF-7 cells were seeded into 6-well plates and were then exposed to Ir-1 at the indicated concentrations (5 or 10 μM) for 4h. After that, the cells were exposed to a 450 nm laser irradiation for 300 s (diode laser, Lasever, 30 J•cm\(^{-2}\)). After the irradiation, the cells were incubated for an additional 20 h at 37 °C under 5% CO\(_2\). Then the cells were collected and washed twice with PBS. The cells were re-suspended in 500 μL annexin binding buffer. The cell suspension was stained with 1 μL annexin V-PE at room temperature for 15 min in the dark and then analyzed immediately by flow cytometry (BD LSRFortessa).

Quantification of singlet oxygen generation (\(\Phi_{\Delta(1^O_2)}\))
A singlet oxygen sensor (DPBF, 1,3-diphenylisobenzofuran), which is highly selective for singlet oxygen, was used to evaluated the singlet oxygen quantum yields (\(\Phi_{\Delta(1^O_2)}\)) of Ir-1. The air-saturated acetonitrile solution of photosensitizer containing DPBF was prepared in the dark and irradiated with 450 nm laser beam in an interval of 10s. DPBF oxidation was monitored by UV-Vis spectrophotometer. The following equation was used to calculate the singlet oxygen quantum yield of the sensitizer with respect to the reference.\(^{[5]}\)

\[
\Phi_{\Delta(1^O_2)}^S = \Phi_{\Delta(1^O_2)}^R \frac{S^S F^R}{S^F F^S}
\]

where \(\Phi_{\Delta(1^O_2)}\) is the quantum yield of singlet oxygen, superscripts “S” and “R” represent Ir-1 and methylene blue (MB) (\(1^O_2\) quantum yield of 0.52 in acetonitrile), respectively. “S” is the slope of a plot of difference in change in absorbance of DPBF (at 411 nm) with the irradiation time, and “F” is the absorption correction factor, which is given by \(F = 1 - 10^{-OD}\) (OD at the irradiation wavelength).
**Detection of ROS generation**

MCF-7 cells were planted on confocal petri dish and incubated with **Ir-1** (10 μM) for 2 h at 37 °C. Then the cells were incubated with 10 μM DCFH-DA for 20 min. After that, the cells were irradiated by the 450 nm diode laser (30 J•cm⁻²). The ROS generation was observed by the fluorescence signal of DCF with CLSM (band path, 500-550 nm).
Cellular uptake mechanism

MCF-7 cells were planted on confocal petri dish and allowed to adhere for 24h. Then the cells were treated under different conditions. After that, the cells were imaged by CLSM.

37 °C: the cells were incubated with \textbf{Ir-1} or \textbf{Ir-2} (10 μM) at 37 °C for 2 h.

4 °C: the cells were incubated with \textbf{Ir-1} or \textbf{Ir-2} (10 μM) at 4 °C for 2 h.

MI (Metabolic inhibitors): the cells were pretreated with 2-deoxy-D-glucose (50 mM) and oligomycin (5 μM) at 37 °C for 1 h and then incubated with \textbf{Ir-1} or \textbf{Ir-2} (10 μM) at 37 °C for 2 h.

NH₄Cl: the cells were pretreated with NH₄Cl (50 mM) at 37 °C for 1 h and then incubated with \textbf{Ir-1} or \textbf{Ir-2} (10 μM) at 37 °C for 2 h.

TEA (tetraethylammonium chloride): the cells were pretreated with TEA (1 mM) at 37 °C for 1 h and then incubated with \textbf{Ir-1} or \textbf{Ir-2} (10 μM) at 37 °C for 2 h.

Synergistic hypoxia and acidity imaging on monolayer cells

MCF-7 cells were planted on confocal petri dish and allowed to adhere for 24 h. For pH imaging, the cells were stained with RPMI-1640 medium containing \textbf{Ir-1} or \textbf{Ir-2} (10 μM) and 0.1% DMSO for 2h at 37 °C, then the cells were further incubated (30 min) with high K⁺ buffers (137 mM NaCl, 120 mM KCl, 10.1 mM Na₂HPO₄, 1.8 mM KH₂PO₄) of different pH values (5.4, 6.4, 7.4, 8.4) in the presence of 10 μM nigericin sodium salt. For hypoxia imaging, after staining the cells with \textbf{Ir-1} or \textbf{Ir-2} (10 μM), the cells were further incubated under three different oxygen conditions (0%, 10%, 21% O₂) for another 1h at 37 °C. Anaero Pack-Anaero and Anaero Pack-Micro aero (Mitsubishi Gas Chemical Co., Inc., Japan) were used to create cell culture environments with oxygen levels of 0% and 10%. For synergistic hypoxia and acidity imaging, the \textbf{Ir-1} or \textbf{Ir-2} stained cells were incubated under hypoxia conditions (0% O₂) for 1h after incubating with high K⁺ buffer of pH 6.4 (containing 10 μM nigericin sodium salt). After that, confocal imaging was conducted with the band path of 650-750 nm upon excitation at 488 nm.
**Generation of 3D multicellular spheroids**

MCSs were cultured using the liquid overlay method. MCF-7 cells in the exponential growth phase were dissociated by a trypsin solution to gain single-cell suspensions. A number of $6 \times 10^3$ diluted MCF-7 cells were transferred to 1.5% agarose-coated transparent 96-well plates with 200 μL of Dulbecco’s Modified Eagle Medium (DMEM) containing 10 % fetal bovine serum. The single cells would generate MCSs approximately 500 μm in diameter at day 4 with 5 % CO$_2$ in air at 37 ℃.

**Synergistic hypoxia and acidity imaging on 3D MCSs**

MCF-7 MCSs of diameters about 500 μm were chosen for synergistic imaging of Ir-1. The medium was carefully replaced with probe supplemented standard medium (Ir-1, 10 μM). After that, the MCSs were incubated for 6 h with 5 % CO$_2$ in air at 37 ℃ to make sure the complex penetrated throughout the spheroids. Then the MCSs were used for hypoxia imaging directly. For synergistic imaging, the medium was removed and the MCSs were washed three times with PBS (pH=7.4). Then the MCSs were further incubated (30 min) with high K$^+$ buffers (137 mM NaCl, 120 mM KCl, 10.1 mM Na$_2$HPO$_4$, 1.8 mM KH$_2$PO$_4$) of pH 6.4 in the presence of 10 μM nigericin sodium salt. All the images were recorded under a 10× objective. Confocal imaging and PLIM were conducted with the band path of 650-750 nm upon excitation at 488 nm (intensity mode) or 405 nm (lifetime mode).

^b The lifetime was measured at 685 nm.

^c The lifetime was measured at 680 nm.
Table S3. Phosphorescence lifetime of Ir-1 (10 μM) and Ir-2 (10 μM) at different pH values in PBS (containing 10% DMSO, v/v) at 25 °C.  $\lambda_{ex} = 405$ nm.

$^a$ All the lifetime values were obtained under 21% oxygen concentration.
$^b$ The lifetime was measured at 685 nm.
$^c$ The lifetime was measured at 680 nm.

Table S4. Phosphorescence quantum yield of Ir-1 (10 μM) at different pH values in PBS (containing 10% DMSO, v/v) at 25 °C under hypoxia and normoxia$^a$.  $\lambda_{ex} = 405$ nm.

<table>

</tbody>
</table>

$^a$ Ru(bpy)$_3$Cl$_2$ ($\Phi=0.018$, $\lambda_{ex}=450$ nm, air-saturated acetonitrile) was used as the standard to obtain the phosphorescence quantum yield values.
$^b$ Hypoxia was achieved via bubbling Ar for 20 min.
$^c$ Normoxia was achieved via bubbling O$_2$ for 20 min.
