Chemicals

Analytical reagents Ni(NO\textsubscript{3})\textsubscript{2}·6H\textsubscript{2}O, Fe(NO\textsubscript{3})\textsubscript{3}·9H\textsubscript{2}O, formamide, NaNO\textsubscript{3}, NaOH, and KOH were purchased from Shanghai Chemical Reagent Co., Ltd (China). IrCl\textsubscript{3} was purchased from Meryer (Shanghai) Chemical Technology Co., Ltd (China). IrO\textsubscript{2} was purchased from Shanghai Macklin Biochemical Co., Ltd (China). All the above chemicals were used as received.

Materials synthesis

A 20 mL aqueous solution contained 0.75 mmol Ni(NO\textsubscript{3})\textsubscript{2}·6H\textsubscript{2}O, 0.25 mmol Fe(NO\textsubscript{3})\textsubscript{3}·9H\textsubscript{2}O and different amounts of IrCl\textsubscript{3} was added dropwise to a solution of 20.0 mL 0.01 M NaNO\textsubscript{3} containing 23 vol% formamide under magnetic stirring at 80 °C. Simultaneously, 0.25 M NaOH aqueous solution was added into the solution to maintain a pH of ~10. The reaction was completed within 10 min. The IrO\textsubscript{x} decorated ultrathin NiFe LDH (IrO\textsubscript{x}/U-NiFe-LDH) was collected by 8000 rpm centrifugation of 10 min and washed with DI water of more than 3 times, then kept in a gel state for subsequent use. For comparison, the synthesis of ultrathin NiFe-LDH (U-NiFe-LDH) was similar to that described above for IrO\textsubscript{x}/U-NiFe-LDH, except the precursor solutions without IrCl\textsubscript{3}. The bulk NiFe-LDH (Bulk-NiFe-LDH) was synthesized as the same without IrCl\textsubscript{3} and formamide. The IrO\textsubscript{x}/C catalyst was prepared as the same method by using 1 mmol active carbon (Vulcan XC-72R) to replace Ni(NO\textsubscript{3})\textsubscript{2}·6H\textsubscript{2}O and Fe(NO\textsubscript{3})\textsubscript{3}·9H\textsubscript{2}O.

Materials characterization

The as-prepared samples were characterized by X-ray diffraction (XRD, Rigaku Ultima III, Japan with CuK\alpha radiation) for crystal structure analysis at 40 kV and 40 mA, X-ray photoelectron spectroscopy (XPS, PHI5000 Versa Probe, ULVAC-PHI, Japan) for composition and chemical states with monochromatized Al K\alpha excitation (The binding energies were corrected by normalizing the C1s spectrum at 284.6 eV, and a Shirley background was used for peak fitting), transmission electron microscope (TEM, FEI Talos F200s equipped with scanning TEM (STEM) for morphology and crystal lattice image, the energy dispersive spectroscopy (EDS) for composition analysis, and the atomic resolution high angle annular dark field (HAADF) images, atomic force microscope (AFM, Asylum Research, MFP-3D-SA, USA) for thickness of nanosheets and Zeta potential and particle size analyzer (ZetaPALS, Brookhaven, USA) for surface potential.

Electrochemical test

The OER catalytic performance was evaluated by linear sweep voltammetry (LSV), cyclic voltammetry (CV) and electrochemical impedance spectroscopy (EIS) on a CHI 660e bipotentiostation. To prepare the catalyst ink, 5 mg of catalyst and 1 mg of conductive carbon (Vulcan XC-72R) was dispersed in 950 µL ethanol by sonication for 20 min and then another ultrasonication after adding 50 µL Nafion (0.125 wt.%, DuPont). Next, 25 µL of ink was dropwise loaded on the carbon fiber paper (0.5 cm × 1 cm) with a microporous layer. After drying, the catalytic working electrode could be used for the electrochemical study. The geometric surface area of catalyst loaded on the carbon fiber paper is 0.5 cm\textsuperscript{2}, and the catalyst loading amount can be calculated as 0.25 mg cm\textsuperscript{-2}. Briefly, the above modified carbon fiber paper electrode as the working electrode, meanwhile an Ag/AgCl (Sat.) electrode and a Pt plate were used as reference and counter electrode, respectively. Before testing, the working electrodes were stabilized after 50 cycles CV treatment. LSV curves were tested in O\textsubscript{2}-saturated 1.0 M KOH solution from 0 to 0.6 V (vs. Ag/AgCl) at a scan rate of 5 mV s\textsuperscript{-1} with inner resistance (IR) compensation (85 %). To evaluate the stability of as-prepared catalysts, the accelerated degradation
testing (ADT) was performed by LSV curves before and after 200, 400, 600, and 800 CV cycles. The EIS was tested in 1.0 M KOH solution by applying an AC voltage of 5 mV amplitude at the potential of 0.51 V (vs. Ag/AgCl) with frequency from 100 kHz to 0.1 Hz. Electrochemical active surface areas (ECSA) were measured by CV in the potential window 0 to 0.2 V (vs. Ag/AgCl) with different scan rates of 20, 40, 60, 80, 100, 120 and 140 mV s\(^{-1}\). The current density at 0.1 V (vs. Ag/AgCl) was used for the calculation. The calculated equation of electrical double-layer capacitance (C\(_{dl}\)) is shown as:

\[
C_{dl} = \frac{j_{nF}}{\nu} = \frac{j_a - j_c}{2\nu}
\]

Wherein, \(j_{nF}\) is the non-Faraday current density, which equal to the half of difference between anodic current density (\(j_a\)) and cathodic current density (\(j_c\)). \(\nu\) is the scan rate. Thus, the \(C_{dl}\) is the slope of the fitting line for \(j_{nF}\) versus different scan rates.

The ECSA can be calculated by:

\[
\text{ECSA} = \frac{C_{dl}}{C_{dl,Ref}}
\]

The turnover frequency (TOF) was calculated by the equation:

\[
\text{TOF} = \frac{j \times A}{4 \times F \times n}
\]

where \(j\) is the current density at 0.53 V or 0.58 V (vs. Ag/AgCl), \(A\) is the geometric surface area of the working electrode, \(F\) is the Faraday constant with a value of 96485 C mol\(^{-1}\), and \(n\) is the mole number of the Ni\(_3\)Fe(OH)\(_8\)NO\(_3\) for IrO\(_x\)/U-NiFe-LDH, U-NiFe-LDH, and Bulk-NiFe-LDH\(^3\). All initial potentials versus Ag/AgCl were standardized to potential versus reversible hydrogen electrode (RHE) by Nernst equation (\(E_{\text{RHE}} = E_{\text{Ag/AgCl}} + 0.197 + 0.059pH\)).
The pattern of Bulk-NiFe-LDH showed peaks at 11.3 °, 22.6 °, 34.4 °, 38.9 °, 46.6 °, 59.8 ° and 61.2 °, corresponding to (003), (006), (012), (015), (018), (110) and (113) facets of NiFe-LDH, respectively. As for the patterns of IrOₓ/U-NiFe-LDH and U-NiFe-LDH, the obvious peaks of (003), (012), (110) and (113) facets indicated that the addition of formamide could not impact the formation of NiFe-LDH species. Meanwhile, the peak of (003) facet was weak in both IrOₓ/U-NiFe-LDH and U-NiFe-LDH, which proved that the NiFe-LDH planes are a few layers. Due to the gel state of IrOₓ/U-NiFe-LDH and U-NiFe-LDH, a wide peak of them ranged at 20 ° ~30 ° represented the scatter of formamide. These facts demonstrated that the formamide could suppress NiFe-LDH layer stacking along the z-axis. Besides, the diffraction peaks of IrOₓ in the IrOₓ/U-NiFe-LDH could not be observed. On the one hand, a few contents of IrOₓ leaded the weak intensity of related diffraction peaks, which were covered by other peaks. On the other hand, IrOₓ species were amorphous state or little clusters, which caused the inferior observability of related diffraction peaks.

All DFT calculations were simulated with the DMol3 software package in Materials Studio. The exchange-correlation energy was described by the GGA function of the PBE, which was supplemented by the rotationally invariant “+U” description. The Hubbard U values were 3.8 eV for Ni 3d orbit and 4.3 eV for Fe 3d orbit. A Ni$_3$Fe-LDH crystal was built for further calculations. According to the AFM results (Fig. 1e, thickness of 1~2 nm), the structure of U-NiFe-LDH contained two Ni$_3$Fe(OH)$_8^+$ planes and one NO$_3^-$ interlayer. Thus, the unit cell of U-NiFe-LDH had been built with a=6.09 Å, b=6.11 Å, c=7.28 Å and α=β=90 °, γ=120 °. The (001) facet of U-NiFe-LDH was modeled by applying a (2×2) surface structure with a vacuum slab of 15 Å along the z-axis. The Brillouin zone was sampled using a grid of 4×4×1 Monkhorst-Pack type of k-points. The structure of IrO$_x$/U-NiFe-LDH was modeled by adding some IrO$_x$ groups at the surface of the U-NiFe-LDH (001) facet. The structure optimization was based on an energy tolerance of $1\times10^{-5}$ Ha, a force tolerance of 0.002 Ha/Å and a displacement tolerance of 0.005 Å. (1 Ha=27.2114 eV)
