S3. Deactivation of CALB

*Lowry’s protein detection method*

Amount of lipase in the filtrate was calculated via Lowry’s method of protein detection using a UV-VIS technique. UV-VIS spectra were performed using Jasco V-650 spectrophotometer at room temperature in aqueous solution and the absorbance at wavelength $\lambda=670$ nm was measured. This technique confirmed the protein was below the detection limit in the filtrate after all reaction cycles.

*Preparation of the calibration curve for Lowry’s protein detection method*

To the 25 mL flask an aqueous solution of 3-30 µL/mL of *Candida antarctica* lipase B was introduced. The calibration curve was made via mixing of 1 mL of protein solution with 5 mL of 2% solution of $\text{Na}_2\text{CO}_3$ in 0.1 M aqueous solution of NaOH. After 10 min, a 0.5 mL of Folin-Ciocalteu reagent was added and the absorbance at wavelength $\lambda=670$ nm was measured after 30 min. Each measurement was repeated twice and the calibration curve with $R^2$ equal 0.979 was achieved in consequence.

S8. The influence of the stirring speed on the reaction rate

Fig. S27 The influence of the stirring speed on the reaction rate.

Reaction conditions: α-AL 0.098 g (1 mmol), n-BuOH 0.149 g (2 mmol), toluene 1 mL/1 mmol of α-AL, biocatalyst 0.150 g/1 mmol of α-AL, 20 °C. All experiments were triplicated (standard deviation 1%).

S9. The influence of the molar ratio of reactants

In Table S3 the composition of the post reaction mixture obtained using various molar ratio of α-Al to n-BuOH from 1:1 to 1:8 and in n-butanol as solvent was presented. Due to the lack of a calibration curve for pseudo-n-butyl levulinate (pseudo-BLV) the raw estimation was performed based on the ratio of peak area on the GC chromatogram.

without toluene

*Reaction conditions:* α-AL 0.098 g (1 mmol), toluene 1 mL/1 mmol of α-AL, CALB/MWCNT-PTFE(0.10 wt.%) biocatalyst 0.150 g/1 mmol of α-AL, 20 °C, 250 rpm. All experiments were triplicated (standard deviation 2%). Shortcuts: LA-levulinic acid, pseudo-BLV- pseudo-n-butyl levulinate.

These experiments clearly showed that two-fold molar excess of n-BuOH in respect to the α-AL is required in order to achieve nearly stoichiometric yield of corresponding ester. Higher concentration of n-butanol in the reaction environment negatively affected activity of biocatalyst. On the other hand, equimolar amounts of both reagents led to the presence of traces the α-AL in the post-reaction mixture, as well as poorer selectivity and formation of significant amounts of pseudo-BVL.
S10. The influence of the amount of CALB immobilized on the MWCNT-PTFE(0.10 wt.%) hybrid support on the biocatalyst activity

In the next step, series of experiments with biocatalysts containing various lipase loadings were performed (Figure S28) with a simultaneous determination of CALB loading via TGA analysis (Table S4). For this purpose, MWCNT-PTFE(0.10 wt.%) was chosen as a hybrid support. The biocatalysts were prepared using different mass of CALB in the relation to the hybrid support (CALB:MWCNT-PTFE(0.10 wt.%); mass ratio MR from 1:1 to 10:1) in the immobilization step.

![Graph showing the influence of mass ratio on conversion](image)

**Fig. S28** The influence of the mass ratio of CALB and MWCNT-PTFE(0.10 wt.%) support in the immobilization step on the activity of biocatalyst in the synthesis of *n*-butyl levulinate.
Reaction conditions: α-AL 0.098 g (1 mmol), n-BuOH 0.149 g (2 mmol), toluene 1 mL/1 mmol of α-AL, biocatalyst 0.050 g/1 mmol of α-AL, 20 °C, 250 rpm. All experiments were triplicated (standard deviation 1%). The yield of n-butyl levulinate at the end points is given in brackets.

**Table S4** The influence of MR (mass of CALB in the relation to the mass of hybrid support CALB:MWCNT-PTFE(0.10 wt.%) used in the immobilization step on CALB loading in biocatalysts (MR determined via TGA/DTG analysis).

</table>

The experiments were carried out in the presence of a lower amount of biocatalyst than the optimal one, in order to slow down the reaction and to present, in the more pronounced manner, the differences between activities of the corresponding catalytic systems. The most promising results were achieved when CALB/MWCNT-PTFE(0.10 wt.%) MR = 7.5:1 was used as biocatalyst. In fact, higher amounts of CALB led to the use of higher amounts of the enzyme without any significant influence on the reaction rate clearly showing the saturation point as well as *plateau* in the activity. On the other hand, smaller amounts of CALB in biocatalyst were insufficient. Furthermore, TGA analysis confirmed the highest amount of lipase in CALB/MWCNT-PTFE(0.10 wt.%) MR = 7.5:1 catalyst and almost the same amount of CALB immobilized using MR 10:1 what is consistent with the results of its activity.
S11. The influence of the biocatalyst loading

The studies concerning the influence of the amount of biocatalyst were carried out with the use of CALB/MWCNT-PTFE(0.10 wt.%) catalyst (0.010-0.200 g per 1 mmol of α-AL) (Figure S29). The highest reaction rate was obtained when 0.150 g of the biocatalyst was applied. Here again, higher amount of the biocatalyst led to obtain approximately the same conversion of α-AL in the same time.

![Graph showing conversion of angelica lactone (%) vs. time (min)](image)
