Chemicals

Aerosil® 200 was a generous gift from Evonik Industries AG (Germany). Trimethoxy(octadecyl)silane (90%), Sodium hydrogenophosphate (98+) and sodium dihydrogenophosphate (99%) were purchased from Aldrich (USA). (3-mercapto-propyl)trimethoxysilane (99%) were purchased from Alfa Aesar (USA). Amberlite IRA-400 (Cl-) ion exchange resin and dodecyl trimethylammonium bromide (99%) were purchased from Alfa Aesar (USA). Tungstophosphoric acid, phosphoric acid and ammonium phosphate dibasic (>99%) were supplied by Acros (USA). Cyclohexene and cyclooctene (98%) were purchased from TCI (Japan). Hydrogen peroxide (50%) was procured from VWR International (France). DMSO-d6 (99.8%) and CDCl3 (99.8%) were purchased from Eurisotop (France) and were used for NMR analysis. All other chemical were purchased from Sigma-Aldrich and used without further purification. Millipore water (18.2 MΩ/cm; Simplicity 185) was used for preparing the particles and emulsions.

Synthesis of functionalized C12-POM NPs, [C12][H2PO4] and [C12]2[HPO4]

The protocol for preparing C12-POM NPs was adapted from a previous study. Briefly, dodecyltrimethylammonium bromide [C12][Br] (19.5 mmol) was dissolved in water (100 mL). An aqueous solution of [C12][Br] was eluted on a hydroxide ion exchange resin to obtain an aqueous solution of [C12][OH]. An aqueous solution of H3[PW12O40] (~6.5 mmol, 10^-4 M) was added dropwise (3 mL/min) to the aqueous [C12][OH] solution (3 × 10^-4 M) until pH 7 at 25 °C under dry Ar and vigorous magnetic stirring (1,500 rpm). The colourless precipitate of tri(dodecyltrimethylammonium) phosphotungstate formed within a few minutes was washed with water and lyophilized (Yield: 99%).

The protocols for preparing [C12][H2PO4] and [C12]2[HPO4] are the same than for C12-POM except that the aqueous solution of H3[PW12O40] is replaced by an aqueous solution of H3[PO4]. Molar ratios of 1:1 and 2:1 are used to obtain dodecyltrimethylammonium dihydrogen phosphate and di(dodecyltrimethylammonium) hydrogen phosphate, respectively. White precipitate are obtained, washed with water and lyophilized (Yield : 99% and 98% respectively).

Synthesis of functionalized silica NPs (C18/C3SO3H)

The protocol for preparing C18/C3SO3H NPs was adapted from a previous study. Briefly, trimethoxy(octadecyl)silane (16 mmol) and (3-mercapto-propyl)trimethoxysilane (4 mmol) were hydrolysed in a 100-mL water/ethanol (1:1 v/v) solution (pH 9.6) at room temperature overnight. The mixture was added dropwise to a suspension of Aerosil®200 (1 g / 50 mL water / 50 mL ethanol, pH 9.6), and was stirred for 24 h under reflux. After grafting, the suspension was cooled down and the white solid was filtered, washed with ethanol (3 x 30 mL) and acetone (30 mL), and dried overnight at 80 °C. The dried powder was grinded and the thiol groups were oxidized using 60-mL of an aqueous solution of H2O2 (50 wt%). Acetonitrile was added dropwise until a homogeneous suspension was
obtained (3 to 4 mL). The reaction mixture was stirred at 40 °C for 24 h. After the synthesis, the powder was filtered, washed with ethanol and dried (Yield: 98%).

**Characterization of NPs**

Thermogravimetric analysis (TGA) was carried out on a Q50 (TA Instrument, US) by heating the samples from room temperature to 900 °C at a rate of 10 °C/min under air atmosphere (100 mL(STP)/ min). The zeta potential of the samples was measured on a Zetasizer (Nano ZS ZEN 3600, Malvern, UK) equipped with a 4.0 mW He-Ne laser light source with a wavelength $\lambda = 632.8$ nm. The measurements were performed by dispersing the nanoparticles in water at 25 °C in the presence of the additives at constant ionic strength (1.0 mS/cm). The acidity of the $\text{C}_{18}/\text{C}_{3}\text{SO}_3\text{H}$ NPs was measured using aliquots, where 50 mg of the NPs were stirred with NaCl (5.85 g / 20 mL ethanol / 30 mL water) at room temperature for 24 h. Then, the NPs were filtered off and the resulting solution was titrated with a 0.025 M NaOH solution using a pH-meter (Meterlab PHM250 Ion Analyzer, Radiometer Analytical).

**Preparation and characterization of emulsions**

To generate Pickering emulsions, water (2.25 mL) and toluene (0.75 mL) were weighed before adding $\text{C}_{12}$-POM and/or $\text{C}_{18}/\text{C}_{3}\text{SO}_3\text{H}$ NPs (50 mg each, 3.6 wt.%). The emulsification was performed using an Ultraturrax T10 basic at 20 °C and 11,500 rpm for a given time (IKA Works, Inc., Germany) in a 5-mL sealed container. To destabilize the emulsions, these were centrifuged at 4,000 rpm for 20 min using a Sigma 2-16PK apparatus.

The type of emulsion was inferred by observing the evolution of a drop of each emulsion when a volume of either oil or water was added (dilution test). Microphotographs were taken using a light microscope Standard 25 ICS (Carl Zeiss AG, Germany) coupled with an Axiocam ERC-5s camera (Carl Zeiss AG, Germany). The emulsions were diluted with the continuous phase before observation and several photographs were taken in different locations to acquire a general view of the droplets. The images were analysed with ImageJ software (National Institutes of Health, USA). The distribution function (log-normal, defined by eq 1) of droplet diameters was obtained by treatment of at least 250 individual droplets using OriginPro 8® software.

$$y = \frac{A}{\sqrt{2\pi \omega d}} \exp\left(-\frac{\ln\left(\frac{d}{d_m}\right)^2}{2\omega^2}\right)$$

where $y$ is the density function, $\omega$ is the polydispersity (the peak will be approximately symmetric when $\omega$ is small), $d_m$ is the median droplet diameter ($d_m$ refers to the peak centre when the log-normal distribution is approximately symmetric), and $A$ is the amplitude corresponding to the area under the integrated curve.

The emulsion stability was examined by the evolution in the emulsion volume fraction as a function of storage time at 60 °C to simulate the reaction conditions.
Finally, the pH of the emulsions was measured in the presence of the additives after stabilization using a pH-meter (Meterlab PHM250 Ion Analyzer, Radiometer Analytical). The pH was measured by adding 1 wt% emulsion in deionized water.

**Catalytic tests**

In a typical catalytic test, toluene (0.75 mL) containing the given cycloalkene (2 mol/L) and water (2.25 mL) containing 1.2 equiv H$_2$O$_2$ (2.4 mmol, 50%) was added to a 5-mL flask and placed in a thermoregulated Lauda RC6 water bath, followed by C$_{12}$-POM and/or C$_{18}$/C$_3$SO$_3$H NPs (50 mg each). The system was pre-emulsified using an Ultra-Turrax® (IKA T 25) at 11,500 rpm for 1 min. The reactor was sealed, heated at 65 °C for 4 h under stirring (500 rpm) to epoxidize the double bond. Then, another 3.5 equiv. H$_2$O$_2$ (7 mmol, 50%) was added to the system, this was re-emulsified and the reaction was pursued at 80 °C for a given time (12 h for cyclohexene and 24 h for cyclooctene) under stirring (500 rpm). The composition of the organic and aqueous phases was analysed along the reaction by $^1$H NMR after decantation. CDCl$_3$ and deuterated DMSO were used as solvents for each phase, respectively, whereas n-dodecane and n-dodecanol were used as internal standards. All the catalytic tests and analyses were carried out at least three times to ensure repeatability.
