1. Recyclability of adsorbents

The reuse of H\textsubscript{4}Ti\textsubscript{5}O\textsubscript{12} nanorods was performed based on desorption and regeneration processes. Firstly, 0.8 g H\textsubscript{4}Ti\textsubscript{5}O\textsubscript{12} was added into 400 mL LiCl solution (pH 13) with initial concentration of 24 mM, and equilibrated for 4 h. Afterwards, the H\textsubscript{4}Ti\textsubscript{5}O\textsubscript{12} after Li\textsuperscript{+} adsorption was immerged into 0.2 M HCl solution and stirred for 24 h to carry out the regeneration process. Then, the sample was collected by centrifugal and white precipitates were washed by ethanol and deionized water for three times, respectively. Then the precipitates were dried in an oven at 60°C for 12 h. In the next reutilization experiments, the volume of LiCl solution was obtained according to adsorbent dosage (In this study, H\textsubscript{4}Ti\textsubscript{5}O\textsubscript{12} dosage was 2 g/L), and reuse process was repeated the above steps.

treatment.

Fig. S2 shows the TEM images of Li₄Ti₅O₁₂. Fig. S2a-d shows sheet-like shape with large surface area, which matches well with the SEM results. The lattice spacing of nanosheet are 2.96 nm and 2.52 nm in Fig. S2e, which can be concluded to (220) and (-311) or other equivalent crystal planes, respectively. Fig. S2f also concludes similar (220) and (3-11) facets of Li₄Ti₅O₁₂ and this nanosheets can be concluded that the exposed facet of Li₄Ti₅O₁₂ nanosheets is (1-14) (inset in Fig. S2d). From the above results, the morphology of Li₄Ti₅O₁₂ is nanosheets with the high-index (1-14) facet exposed.

**Fig. S2** (a)(b)(c)(d) TEM images of Li₄Ti₅O₁₂ (e) and (f) high-resolution TEM imagines of Li₄Ti₅O₁₂. The inset images of (e) is FFT and the inset of (f) is Li₄Ti₅O₁₂ (1-14) facet.

**Computer methods and details**

Density functional theory (DFT) $^{1,2}$ calculations were implemented by the Vienna Ab-initio Simulation Package (VASP) with the projector-augmented wave (PAW) $^{3}$ method, and the Perdew-Burke-Ernzerh (PBE) exchange-correlation functional $^{4}$ of the
Generalized Gradient Approximation (GGA)\(^5^7\). Owing to the strong-correlation d-electrons of Ti metals, the Hubbard-type U correction was adopted. In order to gain accurate computation, the U values of 2.5 eV were used\(^8^9\). The cutoff energy of 500 eV was adopted in all calculations. The thickness of the vacuum is set to the 15 Å. An appropriate k-point mesh of \(3\times3\times1\) for the \(\text{Li}_4\text{Ti}_5\text{O}_{12}\) (1-14) surface was adopted, respectively. In order to improve the quality of charge density, the k-point mesh of \(4\times4\times1\) was adopted. The electronic total energies convergence criterion was set at \(10^{-4}\) eV. The atomic positions were stable until Hellmann-Feynman forces on each atom were less than a threshold value of 0.01 eV. The adsorption energy (\(E_{\text{ads}}\)) for Li adsorbed on optimized (1-14) surface slab of \(\text{H}_4\text{Ti}_5\text{O}_{12}\) is calculated as Eq. (1):

\[
E_{\text{ads}} = E_{\text{(Adsorbate/substrate)}} - [E_{\text{(Adsorbate)}} + E_{\text{(substrate)}}]
\]
