S7. General procedure for the pyrolysis in a quartz tube at 750 °C

All the procedures were performed under argon atmosphere. The furnace was preheated to 750 °C, then, a polymer sample was placed in a part of the tube, and the tube was placed in the furnace (in the case of polyvinyl bornyl and myrtanyl substrates: first, a place of a tube was preheated, which does not contain a sample, and then shifted the tube further and heated the part with a sample).

Polyvinyl menthol (1b): loading 25 mg, rapid heating to 415 °C, then heating to 650 °C for 5 minutes, then 5 min to 720 °C, then a very slow increase of temperature. A yellow liquid appeared on the walls of the extended part of the tube. After 30 min of the pyrolysis, the tube was removed and cooled. There was no residue in the part of the tube that originally contained the sample. The liquid part was washed off with methylene chloride, the solvent was evaporated, and samples were taken for NMR and chromatography (in ethyl acetate).

Polyvinyl borneol (2b) and polyvinyl myrtanol (6b): loading 20 mg, rapid heating to 745 °C, then very slow increase of temperature. A yellow liquid appeared on the walls of the extended part of the tube. After 30 min of pyrolysis, the tube was removed and cooled. There was no residue in the part of the tube that originally contained the sample. The liquid part was washed off with methylene chloride, the solvent was evaporated and samples were taken for NMR and chromatography (in ethyl acetate (polyvinyl borneol) and methylene chloride (polyvinyl myrtanol) due to low solubility in EA. 150 mg of polyvinyl borneol (2b) were disassembled in a quartz tube in the same manner at 400 °C bubbling the gas phase through chloroform-d and toluene-d₆.
