1. General information

Unless otherwise indicated, all the regents and solvents were purchased from commercial suppliers and used without any further purification. $^1$H spectra were recorded in CDCl$_3$ or (Methyl sulfoxide)-d6 on 400MHz NMR spectrometers and resonances ($\bullet$) are given in parts per million relatives to tetramethylsilane. Data are reported as follows: chemical shift, multiplicity (s = singlet, d = doublet, t = triplet, q = quartet, p = penta, dd = doublet of doublets, dt = doublet of triplets, ddt = doublet of doublet of triplets, dtd = doublet of triplet of doublets, m = multiplet, br = broad), coupling constant (J) in Hertz (Hz), and integration. $^{13}$C NMR were recorded at 100 MHz and chemical data for carbons are reported in parts per million (ppm, $\delta$ scale) downfield from tetramethylsilane and are referenced to the carbon resonance of the solvent. Column chromatography was generally performed on Silicycle silica gel (200-300 mesh). Analytical thin-layer chromatography (TLC) was performed on 0.2 mm coated silica gel plates (HSGF 254) and visualized the course of the reactions using a UV light (254 nm or 365 nm). High-resolution mass spectra (HRMS) were obtained on an Agilent mass spectrometer using ESI-TOF (electrospray ionization-time of flight).

<sup>a</sup> Reaction conditions: undivided cell, graphite anode, Pt plate cathode, constant current = 15 mA, 1a (0.5 mmol), 2a (1.5 mmol), electrolyte (1.0 mmol), solvent (10 mL), under air, room temperature, 3h. <sup>b</sup> Isolated yield. <sup>c</sup> N₂ instead of air.

A series of conditions including electrode, electrolyte, current, solvent and reactant equivalent ratio were also screened in a batch reactor. The N-Alkyl-N-methacryloyl benzamides 1a and 4-methylbenzenesulfonyl hydrazide 2a were chosen as the model reaction to search for optimal reaction conditions. With nBu₄NPF₆ as the electrolyte and the current of the 15 mA, a series of solvents were explored. The results disclosed that the cosolvent of CH₃CN/H₂O (v/v=3:1) might be the best choice (Table S1 entries 1-8). Moreover, the effect of
various electrolytes was also investigated. However, the other electrolytes such as LiClO$_4$, nBu$_4$NBF$_4$ and nBu$_4$NI could not improve the yield of 3a (Table S1 entries 9-11). Compared with the reaction condition of 15 mA, the reaction conditions of 5, 10, and 20 mA all resulted in a lower conversion (Table S1, entries 13–15). Further exploration focused on electrochemical parameters, and the reaction was shown to fail to proceed without the applied constant current (Table S1, entry 12). Either decreasing or increasing the equivalents of nBu$_4$NPF$_6$ led to lower yield (Table S1, entries 16–17). In addition, the reaction with different electrodes could resulted in a drop of the yields of product 3a (Table S1 entries 18-21). Finally, N$_2$ atmosphere instead of air was tested, and the results show that the yield of product 3a was no obvious change (Table S1 entries 22).

3. Electrochemistry continuous flow system

Reactions are performed in a novel flow electrochemistry system (the Asia Flux module). This system includes pumps, flow cell, working prototype cell holder and control module. The flow cell consists of pairs of electrodes separated by a gasket. Electrode materials include stainless steel, carbon, magnesium and stainless steel with a platinum coating (also discussing copper, tin, and titanium) and the cell can be divided by a membrane to isolate the chemistry at the anode from the chemistry at the cathode. The working prototype cell holder holds the electrodes in place, enables quick fluidic and electrical connections and locates in the syrris range of temperature controllers (e.g. The Asia Chip Climate Controller). The control module controls the current/voltage applied to the electrodes, displays the temperature and locates the holder on the front of the module for room temperature applications.

4. General procedure for the synthesis of product 3a in electrochemistry continuous flow system

**General procedure for synthesis of N-methyl benzamide**

A 100-mL round bottom flask was charged with methylamine hydrochloride (15 mmol), K$_2$CO$_3$ (20 mmol) in Ethyl acetate (20 mL) and H$_2$O (10 mL) and benzoyl chloride (10 mmol) was added slowly to the reaction mixture at 0°C. After that, the residue was stirred at room temperature for 4-6 h. The reaction was completed by TLC monitoring, the organic phase was separated, dried over MgSO$_4$, and concentrated under vacuum. The resulting residue was purified by flash silica gel column chromatography (eluent: petroleum ether/ethyl acetate = 1: 1) to afford the desired products with 93% yield.

**General procedure for synthesis of N-methacryloyl-N-methylbenzamide 1a**

A 100-mL round bottom flask was charged with N-methyl benzamide (10 mmol), DMAP (1 mmol), triethylamine (20 mmol) in dichloromethane (20 mL) and methacryloyl chloride (15 mmol) was added slowly to the reaction mixture at 0°C. After that, the residue was stirred at room temperature for 4-6 h. The reaction was completed by TLC monitoring, the organic phase was separated, dried over MgSO$_4$, and concentrated under vacuum. The resulting residue was purified by flash silica gel column chromatography (eluent: petroleum ether/ethyl acetate = 3: 1) to afford the desired products 1a with 77% yield.

**General procedure for the preparation of sulfonyl hydrazides 2a**

Sulfonyl hydrazides were prepared according to a literature procedure. The
hydrazinemonohydrate (30 mmol) was added dropwise into the solution of sulfonyl chloride (10 mmol) in THF (50 mL) under nitrogen at 0 °C. Subsequently, the mixture was further stirred at 0 °C for 30 minutes. After the completion of the reaction, the solvent was removed by evaporation, and the residue was extracted with dichloromethane (3 x 20 mL), and the combined organic layer was washed with water, and brine, and dried over Na₂SO₄. Concentration in vacuum followed by silica gel column chromatography (eluent: petroleum ether/ethyl acetate = 1: 1) to give the desired product 2a in yields range from 70-95%.

**General procedure for the synthesis of product 3a in electrochemistry continuous flow system**

![Chemical structure diagram](image)

First, assembled and installed the flow electrochemistry device, the anode as graphite plate, cathode as platinum plate and the cell volume was 225 μL. Second, 1a (0.5 mmol), 2a (1 mmol, 2 equiv.) and nBu₄NPF₆ (1.0 mmol, 2 equiv.) were dissolved in CH₃CN/H₂O (10 mL, v/v = 3/1). The reaction mixture was pumped into the flow cell via a syringe and electrolyzed at a constant current of 15 mA at room temperature. The flow rate was 225 μL/min and residence time 1 minute. The out flow of the reaction mixture was collected. The solvent was removed with a rotary evaporator. The pure product 3a was obtained by flash chromatography on silica gel column chromatography (eluent: petroleum ether/ethyl acetate = 3: 2).

**5. Procedure for cyclic voltammetry (CV)**

Cyclic voltammetry was performed in a three-electrode cell connected to a schlenk line under nitrogen at room temperature. The working electrode was a steady glassy carbon disk electrode, the counter electrode a platinum wire. The reference was an Ag/AgCl electrode submerged in saturated aqueous KCl solution. (1) A mixed solvent (MeCN/H₂O = 3/1, 10 mL) containing nBu₄NPF₆ (1 mmol) were poured into the electrochemical cell in cyclic voltammetry
experiments. The scan rate was 0.10 V/s, ranging from 0 V to 2.5 V. (2) 1a (0.5 mmol) and a mixed solvent (MeCN/H₂O = 3/1, 10 mL) containing nBu₄NPF₆ (1 mmol) were poured into the electrochemical cell in cyclic voltammetry experiments. The scan rate was 0.10 V/s, ranging from 0 V to 2.5 V. (3) 2a (1 mmol) and a mixed solvent (MeCN/H₂O = 3/1, 10 mL) containing nBu₄NPF₆ (1 mmol) were poured into the electrochemical cell in cyclic voltammetry experiments. The scan rate was 0.10 V/s, ranging from 0 V to 2.5 V.
