Self-Healable Transparent Polymer/Salt Hybrid Adhesive via Ternary Bonding Effect

Supporting Information

1. Supplemental characterization methods

The glass transition temperature of the hybrids was measured using differential scanning calorimeter (DSC, Mettler Toledo DSC 1). Approximately 5 mg samples were heated over the temperature range of 20 °C to 180 °C with a heating rate of 10 °C min⁻¹ in a nitrogen atmosphere. The moisture uptake was tested by putting the film samples into a humidity chamber with T=25 °C and RH=95% ± 2% for 24 h. The films were weighed to a precision of 0.1 mg before and after the tests. The moisture uptake percentage of the hybrids were calculated by the weight change rate using equation (1):

\[
\frac{W_t - W_0}{W_0} \times 100\% 
\]

where \(W_t\) is the weight of film after 24 h-test and \(W_0\) is the original weight of the film.

Raman spectrum was recorded by Renishaw inVia Raman spectrometer. The micro-morphology of the samples was studied by scanning electron microscope (SEM, FEI Nova NanoSEM 450). For the measurement of elemental concentration, 1.1418 g mixture of soil and plaster from ancient wall painting was dissolved in 30 mL deionized water and stirred for 24 h. After centrifugation, the supernatant was collected for further analysis. Thermo Fisher ICS-1100 ion chromatography system was adopted in the analysis of the anions’ concentration. The concentration of cation elements was measured by Agilent 7700 ICP-MS MassHunter Workstation.
2. Supplemental results and discussion

The DSC was adopted to characterize the miscibility of the hybrid materials. The glass transition temperature \((T_g)\) of a blend material indicates the miscibility of different portions. Fig. S1a shows the DSC curves of the hybrids at different PHS/PEOZ ratios, and the \(T_g\) values are recorded in Table S1. All the hybrids displayed a single \(T_g\), which implies that the hybrids of PEOZ and PHS are in single-phase and have good miscibility.

**Fig. S1.** Characterization of the hybrids. **a)** DSC curves of the neat polymers and hybrids. **b)** FT-IR spectra of films of neat polymers and hybrids, **c)** the peaks of carbonyl shift due to the hydrogen bonding. In each graph, **a**, **b**, **c**, **d**, **e**, and **f** refer to PEOZ, 15PHS/PEOZ, 30PHS/PEOZ, 50PHS/PEOZ, 70PHS/PEOZ, and PHS, respectively.
**Table S1.** The glass transition temperature of the hybrids with different PHS/PEOZ ratios.

Then the hybrid series were characterized by Fourier Transform Infrared Spectroscopy (FTIR) spectroscopy. The peak at 1624 cm$^{-1}$ is assigned to the C=O stretching band of PEOZ (Fig. S1b, curve a), and the peaks at 1591 cm$^{-1}$ and 1608 cm$^{-1}$ refer to the C=C vibration of the benzene ring of PHS (Fig. S1b, curve f). There are no new chemical bonds produced within the hybrid system; therefore, PEOZ does not chemically react with PHS. As the proportion of PHS is increased, the C=O stretching band of PEOZ shifts slightly to lower wavenumber (Fig. S1c). Meanwhile, in the OH stretching region, the inter-associated O-H bond of PHS is observed at 3273 cm$^{-1}$ (-OH⸱⸱⸱HO-) of curve f. The peaks move to lower wavenumber with the increasing of PEOZ up to 50 wt% (Fig. S1b, curve d), which demonstrates that more hydroxyl groups involve in the hydrogen bonding with the carbonyl groups of PEOZ. Several reports also confirmed the hydrogen bonding site of the tertiary amide with phenol is on oxygen.$^{2-4}$ And the position of this bonded -OH group remains stable with more than 70 wt% PEOZ (curve c), which means that -C=O⸱⸱⸱HO- is predominant in the hydrogen bonding. It is proven that PEOZ and PHS are miscible due to hydrogen bonds.$^5$
Fig. S2. Optical photographs of the self-healing process of a) 15PHS/PEOZ, b) 30PHS/PEOZ, c) 50PHS/PEOZ, and d) 70PHS/PEOZ. 50PHS/PEOZ and 70PHS/PEOZ show no self-healing ability after 6 h. Scale bar: 100 μm.
The moisture uptake of the hybrid films was studied (Fig. S3a). PEOZ absorbs 19.43% of moisture after being put in the humidity chamber (RH≈95%) for 24 h and becomes gel-like and sticky due to its high hydrophilicity. In comparison, the moisture up-taken of 30PHS/PEOZ decreases dramatically to 2.13%. For the hybrids of 50PHS/PEOZ and 70PHS/PEOZ, the moisture up-taken reduce to 1.68% and 0.34%, respectively. Besides, the adhesion strengths of PEOZ and the hybrids in a wet environment were tested by the single-lap tensile shear strength test (Fig. S3b). After being put in the humidity chamber (RH≈95%) for 24 h, the pure PEOZ bonded specimens easily get separated, and the adhesion strength is only about 0.041 ± 0.016 MPa. The strength increases to 0.360 ± 0.061 MPa when the hybrid 30PHS/PEOZ is used and does not change much when more PHS is added (i.e., 50PHS/PEOZ and 70PHS/PEOZ).
Fig. S4. Optical images of the scratch on the 30PHS/PEOZ film for the self-healing test in the environment at 35 °C, RH 54%. The film of 30PHS/PEOZ cannot heal completely in 3 h, which is longer than in the RH 95% environment (70 min). These parameter settings are as the same dew point with 25 °C, RH 95%.

**Fig. S9.** Solid state $^{13}$C NMR spectra of 30PHS/PEOZ and 30PHS/PEOZ+CaCl$_2$. All peaks are assigned to the structure of PHS and PEOZ$^5$. The s stands for the solvent DMF remained in the samples.
Fig. S10. $^1$H NMR spectra of 30PHS/PEOZ and 30PHS/PEOZ+CaCl$_2$ in DMSO-d$_6$. Peak assignments are according to references $^7$ and $^8$. 
**Fig. S11.** a) The poor film-forming of PHS+CaCl$_2$. It is impossible to implement the tensile test nor even after adding CaCl$_2$. b) The comparisons of PEOZ vs. PEOZ+CaCl$_2$ and 30PHS/PEOZ vs. 30PHS/PEOZ+CaCl$_2$ in the tensile tests. The soft and flexible properties of PEOZ have not been modified when only the metal-ligand coordination and ionic bond exist. By comparison, the hydrogen bonds between PHS and PEOZ strengthens PEOZ obviously. On this basis, the ternary molecular interaction, which is induced by CaCl$_2$, further enhances the mechanical strength of PHS/PEOZ to a higher level.
Fig. S12. Comparison of the self-healing rate among a) neat 30PHS/PEOZ and the blends containing b) Ca(NO$_3$)$_2$, c) NaCl, d) CaCl$_2$, and e) MgCl$_2$, respectively. Scale bars: 100 μm.
