General experimental procedures

Unless otherwise noted, materials were obtained from commercial suppliers and used without further purification. The instrument for electrolysis was dual display potentiostat (QJ3005T) (made in China). The anodic electrode was platinum plate (10 mm×10 mm×1 mm) and cathodic electrode was platinum plate (10 mm×10 mm×1 mm). Thin layer chromatography (TLC) employed glass 0.25 mm silica gel plates. Flash chromatography columns were packed with 200-300 mesh silica gel in petroleum (boiling point was between 60-90 °C). Gradient flash chromatography was conducted eluting with a continuous gradient from petroleum to the indicated solvent, and they were listed as volume/volume ratios. 1H- and 13C-NMR spectra were recorded on a Bruker DRX-400 spectrometer operating at 400 MHz and 100 MHz respectively. HRMS spectrometry (LC-HRMS) was recorded on a LXQ Spectrometer (Thermo Scientific) operating on ESI-TOF (MeOH as a solvent).

General procedure for the synthesis of compounds 3a-r.

In an oven-dried undivided three-necked bottle (25 mL) equipped with a stir bar, P(O)H compounds 1a (0.5 mmol), phenol 2a (0.6 mmol), sodium iodide (0.2 equiv), MeCN (5 mL) was added. The bottle was equipped with platinum plate (10 mm×10 mm×1 mm) as the anode and platinum plate (10 mm×10 mm×1 mm) as the cathode. The reaction mixture was stirred and electrolyzed at a constant current of 20 mA under air at room temperature for 2 h. After completion of the reaction, as indicated by TLC and GC-MS, the pure product was obtained by flash column chromatography on silica gel (petroleum ether : ethyl acetate = 20-5 : 1). The same procedure was applied to the production of other compounds 3a-r.

General procedure for the synthesis of compounds 5a-p.

In an oven-dried undivided three-necked bottle (25 mL) equipped with a stir bar, P(O)H compounds 1a (0.5 mmol), aniline 4a (0.6 mmol), potassium iodide (0.2 equiv), MeCN (5 mL) was added. The bottle was equipped with platinum plate (10 mm×10 mm×1 mm) as the anode and platinum plate (10 mm×10 mm×1 mm) as the cathode. The reaction mixture was stirred and electrolyzed at a constant current of 10 mA under air at 50°C for 2 h. After completion of the reaction, as indicated by TLC and GC-MS, the pure product was obtained by flash column chromatography on silica gel (petroleum ether : ethyl acetate = 40-30 : 1). The same procedure was applied to the production of other compounds 5a-p.
**General procedure for cyclic voltammetry (CV)**

Cyclic voltammetry was performed in a three-electrode cell connected to a schlenk line under air at room temperature. The working electrode was a glassy carbon electrode, the counter electrode a platinum wire. The reference was a SCE electrode submerged in saturated aqueous KCl solution. 10 mL of CH$_3$CN containing 0.01 M nBu$_4$NBF$_4$ were poured into the electrochemical cell in all experiments. The scan rate is 0.1 V/s, ranging from 0 V to 3.5 V. The peak potentials vs. SCE for used. From figure 1, it can be seen that an obvious oxidation peak of phenol (2a) was observed at 1.82 V. The oxidation peak of aniline (4a) could also be observed at 1.15 V. Meanwhile, the oxidation peak of aniline KI could be seen at 1.05 V.
