Experimental

General

$^1$H- and $^{13}$C-NMR spectra were recorded on a Bruker DPX 300 spectrometer. $[\text{Ru}(\rho$-cymene)Cl$_2$]$_2^1$, $L_1^2$ and $L_2^2$ were prepared according to the literature method. All other reagents are commercially available and were used as received. Microanalyses were performed by Mr Ian Blakeley in the University of Leeds, School of Chemistry. Mass spectra were collected by Ms Tanya Marinko-Covell either on a Bruker Daltonics (micro TOF) instrument operating in the electrospray mode. X-ray data was collected by the author. A suitable single crystal was selected and emersed in an inert oil. The crystal was then mounted onto a glass capillary and attached to a goniometer head on a Bruker X8 Apex diffractor using graphite monochromated Mo-Kα radiation (λ= 0.71073 Å) and 1.0° ϕ-rotation frames. The crystal was then cooled to 150K by an Oxford cryostream low temperature device. The full data set was recorded and the images processed using DENZ0 and SCALEPACK programs. The structures were solved by the author. Structure solution by direct methods was achieved through the use of SHELXS86, SIR92 or SIR97 programs, and the structural model defined by full matrix least squares on $F^2$ using SHELX97. Molecular graphics were plotted using POV-Ray via the XSeed program. Editing of Crystallographic Information files and construction of tables of bond lengths and angles was achieved using WC and PLATON. Hydrogen atoms were placed using idealised geometric positions (with free rotation for methyl groups), allowed to move in a “riding model” along with the atoms to which they were attached, and refined isotropically.

Cell Line Testing

The in vitro tests were performed at the Institute of Cancer Therapeutics, Bradford, on MCF7 (human breast adenocarcinoma) and HT-29 (human colon adenocarcinoma) cell lines. Cells were incubated in 96-well plates at a concentration of $2 \times 10^5$ cells/ml. 200 μL of growth media (RPMI 1640 supplemented with 10% foetal calf serum, sodium pyruvate (1 mM) and L-glutamine (2 mM)) was added to each well and the plates were incubated for 24 hours at 37 °C in an atmosphere of 5% CO$_2$ prior to drug exposure. Compounds 1-6, $[\text{IrCp}'\text{Cl}_2]^2$, $[\text{Ru}(\rho$-cymene)Cl$_2]^2$, 2-hydroxy-1,4-napthoquinone and cisplatin were all dissolved in
dimethylsulphoxide at a concentration of 25 mM and diluted further with medium to obtain
drug solutions ranging from 250 to 0.49 μM. The final dimethylsulphoxide concentration was
0.1% (v/v) which is non-toxic to cells. Drug solutions were applied to cells and incubated for
5 days at 37 °C in an atmosphere of 5% CO₂. 20 μL of MTT (5 mgml⁻¹) was added to each
well and incubated for 3 hours at 37 °C in an atmosphere of 5% CO₂. The solutions were then
removed and 150 μL of dimethylsulphoxide was added to each well to dissolve the purple
formazan crystals. A Thermo Scientific Multiskan EX microplate photometer was used to
measure the absorbance at 540 nm. Lanes containing medium only and cells in medium (no
drug) were used as blanks for the spectrophotometer and 100% cell survival respectively.
Cell survival was determined as the absorbance of treated cells divided by the absorbance of
controls and expressed as a percentage. The IC₅₀ values were determined from plots of %
survival against drug concentration. Each experiment was repeated 3 times and a mean value
obtained.

**Synthesis of C₁₆H₁₄NOF (L3)**

Sodium ethoxide (2.46 g, 36.2 mmol) was dissolved in ethyl acetate (20 ml), and a mixture of
3′-fluoroacetophenone (5.00 g, 36.2 mmol) and ethyl acetate (20 ml) was added dropwise
with stirring over 10 minutes. The reaction mixture was heated under reflux for 1 hour and
allowed to stand at room temperature until a precipitate was observed. The solution was
transferred to a separating funnel with ice water (100 ml) and the aqueous layer was washed
with diethyl ether (3 x 30 ml). The solution was acidified with sulfuric acid (1:1 ice water)
until slightly acidic to litmus. The product was extracted with diethyl ether (4 x 30 ml) and
dried (anhydrous sodium sulfate) in the freezer overnight. The drying agent was removed by
filtration and the solvent was then removed under reduced pressure to give a light brown oil
which readily solidified in air. The crude product was recrystallised from methanol to give
light brown crystals of 3-fluoro-1-phenylbutan-1,3-dione (1.99 g, 11.1 mmol, 31%).

HCl (0.5ml) was added dropwise to a solution of 3-fluoro-1-phenylbutan-1,3-dione (0.52g,
2.89 mmol) and aniline (1 ml) in toluene (10 ml) until a precipitate formed and the mixture
was stirred for 16 hours. The precipitate was filtered and the solvent removed from the
filtrate yielding a brown precipitate. The crude product was recrystallised from slow
evaporation in ethanol (20 ml)to obtain yellow crystals (0.61 g, 2.9 mmol, 83%).
