**Experimental section**

*Synthesis of nitrogen doped carbon coated MgO supports CN@MgO.* In a typical process, 2 g glucosaminehydrochloride (GAH) was firstly dissolved in 15 mL deionized water in a crucible (50 mm in diameter) with stirring, afterwards 0.5 g MgO nanopowder were added in. The crucible was heated to 80 °C in an oil bath with stirring until a dried dark black product was obtained (Figure S1 A for detailed color change process of the above mixture with stirring under heating and Figure S1 B the IR spectras comparison of GAH and the obtained mixture). Afterwards, it was transferred into a nitrogen furnace, calcined at 1000 °C for 1 h with a heating rate of 10 °C/min while keeping a N₂ flow of 400 mL/min, until it was cooled to room temperature, the black product was ground into powder, finally, the CN@MgO(where the mass ratio of MgO in CN@MgO was 0.4)was obtained. For another two supports CN@MgO-1 and CN@MgO-2 (where the mass ratio of MgO in CN@MgO were 0.25 and 0.6, respectively), only the mass ratio of the precursors GAH and MgO were changed to 2/0.33 and 2/0.8, respectively.

*Synthesis of nitrogen doped carbon CN.* Moderate amount of the as prepared CN@MgO was dissolved in an excess diluted HCl solution, after 24 hours’ magnetic stirring at room temperature, filter the solution with deionized water for several times until the pH of the filtrate reached 7, indicating a complete removal of the residual acid. Then a black solid was obtained and it was dried in an oven at 70 °C overnight, finally the black solid was gently ground to obtain a black powder, nitrogen doped CN was obtained.

*Synthesis of Pd/CN@MgO, Pd/CN, Pd/MgO, and Pd/(CN+MgO) catalysts.* In a typical synthesis, 0.2 g CN@MgO was dispersed in 20 mL deionized water in a beaker by shaking it in the ultrasonic sound condition, and then 2 mL PdCl₂ aqueous solution (0.01 g/mL) was added into, 10 minutes later, 10 mL newly prepared NaBH₄ solution (1 mg/mL) was added into the solution, and kept shaking the solution for 30 minutes. All the process above was done in the ultrasonic sound condition. Later, filter the solution and wash the residue (black solids) with deionized water for several times. After being dried in an oven overnight, the catalyst was ready to be used. The rest catalysts Pd/CN, Pd/MgO and Pd/(CN+MgO) were
synthesized in the same method as in the fabricating the Pd/CN@MgO catalyst except that replacing the support CN@MgO with CN, MgO and CN+MgO, respectively. As to Pd/(CN+MgO), quantitative CN and MgO was mixed according to the mass ratio of CN/MgO in Pd/CN@MgO catalyst. For the above Pd/CN@MgO, Pd/CN, Pd/MgO and Pd/(CN+MgO) catalysts, the theoretically loading of Pd was 5.66% in mass ratio, and the actual loading of Pd from ICP analysis were 5.5 %, 4.6 %, 6.0 % and 5.4 %, respectively.

**Catalytic aldol condensation between furfural and acetone.** All aldol reactions were carried out in a 150 mL stainless-steel autoclave with an external temperature and stirring controller. In a typical experiment, a catalyst (20 mg) was first added into a beaker with 40 mL deionized water followed by ultrasound treatment to better disperse nanoparticles in the solution as possible. Afterwards, the solution with well-dispersed nanoparticles were transferred into the autoclave followed by adding 0.31 g furfural and 1.69 g acetone (Molar ratio 1:9). Then the reactor was purged with N$_2$ for 3 times, then sealed tight and pressurized to 0.1 MPa N$_2$, when the temperature was heated to 120 ºC, stirring was started to give a 1 h of reaction. Afterwards, the reactor was carefully vented and the reaction mixture was extracted with ethyl acetate (~40 mL). The furfural conversion and product selectivity were confirmed by GC with cetane as an internal standard. In a series of aldol condensation reactions, reaction parameters such as molar ratio of acetone/furfural, N$_2$ pressure, reaction temperature, and reaction time were studied with the same processing procedures described above.

**Sequential aldol condensation followed by catalytic hydrogenation.** All reactions were carried out in a 150 mL stainless-steel autoclave. Typically, before starting the condensation reaction, the reactor was initially loaded with with reaction mixture of 20 mg Pd/CN@MgO, 0.31 g furfural and 1.69 g acetone in 40 mL deionized water, and air was purged out with N$_2$ for three times. The reactor was then in an atmosphere of 0.1 MPa N$_2$, when heated to 120 ºC, the stirring was started. Aldol condensation was stopped after 1 h of reaction, and the reactor was cooled to room temperature. The following hydrogenation reaction was started by a similar purging procedure with H$_2$ and then pressurized to 1.0 MPa, then the reactor was again heated to 120 ºC, and then stirring was started to let the hydrogenation
run for 3 h. Afterwards, the reactor was cooled to room temperature quickly in water and carefully vented, the reaction mixture was extracted with ethyl acetate (~ 40 mL). The furfural conversion and product selectivity were confirmed by GC with cetane as an internal standard.

**Recycling of Pd/CN@MgO towards the hydrogenation of monomer.** In a typical reaction, 0.1 g of the monomer substrate, 40 mg catalyst and 20 mL water were all added in a 50 mL three-necked flask, and ultrasound treatment was performed to better disperse the mixture. Afterwards, the reaction mixture was subjected to 0.1 MPa H₂ at 80 °C for 1.5 h under magnetic stirring. Finally, the products were extracted with ethyl acetate and the final conversion and product selectivity was confirmed by GC with cetane as an internal standard. As to the recycling procedure, the catalyst Pd/CN@MgO was recycled by centrifugation and washed with ethanol three times, then dried overnight. For each of the recycles, the amount of substrate was reduced in mass proportion with the recycled catalyst, and the hydrogenation procedure was repeated as illustrated above.
**Figure S1.** A) Color change process of the mixture of GAH and MgO with stirring under heating (80 °C). As can be seen in the preparation process, we found that through the slow oligomerization of GAH with the gradual color change when heating, MgO was uniformly wrapped by the polymerized GAH. Finally, only dark brown polymerized GAH wrapped MgO was seen. B) IR spectras of GAH and the final dark brown product. From the decreasing peak intensity around ~ 1040 cm^{-1} which is to C-O stretching vibration, demonstrating GAH was polymerized during heating (80 °C) with MgO.

**Figure S2.** TGA spectras of the synthesized CN@MgO with different mass ratio of CN to MgO in O₂ flow, which were obtained by changing the mass ratio of precursors GAH and MgO. For simplicity, the supports are simplified as CN@MgO, CN@MgO-1, CN@MgO-2, respectively. Where we can see the mass ratio of MgO in each hybrid are about 0.4, 0.25 and 0.6, respectively.

All runs were carried out in 40 mL H₂O with c(furfural)= 0.081mol·L⁻¹ while keeping the molar ratio of furfural/acetone 1:9 and the mass ratio of organic/ catalyst 100:1.
Table S4. Catalytic products of aldol condensation of furfural and acetone followed by hydrogenation with Pd/CN@MgO catalysts with different mass ratio of CN and MgO. The results showed both furfural conversion and products selectivity were worse than what was performed using Pd/CN@MgO as the most desired catalyst, showing the significant influence of the catalyst support on the overall catalytic activity, although with the same components CN and MgO, but if contents between were changed, the results may be much different.
