1. Additional experimental details for the synthesis of different methylthio arylethyynes (MTAs)

Synthesis of terminal function molecule 21. (4-ethynylphenyl)(methyl)sulfane 21 was prepared according to the procedures shown in Scheme S1. Reaction of 4-bromobenzenethiol with CH₃I afforded (4-bromophenyl)(methyl)sulfane, which was then reacted with 2-methylbut-3-yn-2-ol in Sonogashira reaction afforded 20. The propan-2-ol group was next removed with KOH in toluene at 100 °C for 2 hr to give (4-ethynylphenyl)(methyl)sulfane (21).

Synthesis of terminal function molecule 22. Normally, increasing the number of side chains decreases the transition temperatures and increases the solubility. While unsubstituted linear methylthio arylethyynes (MTAs) is poor solubility, the long alkoxy side chains moieties enhances the solubility of the longer linear MTAs. 2,5-dibutoxy-1,4-diiodobenzene was generated by etherification of hydroquinone, iodination with 1,4-dibutoxybenzene. The synthesis proceeded followed by cross-coupling of 21 giving 22. A co-product of 3 could also be produced (Scheme S1).

22 and 3: To a nitrogen purged flask were added 2,5-dibutoxy-1,4-diiodobenzene (1.26 g, 2.65 mmol), (Ph₃P)₂PdCl₂ (91 mg, 0.13 mmol), CuI (25 mg, 0.13 mmol), diisopropylamine (5 mL), and toluene (20 mL). Then, to the above suspension was added a solution of 21 (410 mg, 2.77 mmol) in diisopropylamine (2.5 mL) and toluene (10 mL) over a period of 5 hr at 65 °C by a machine. The
reaction mixture was cooled to room temperature and filtered. The filtrate was poured into aqueous
NH₄Cl, and extracted with ethyl acetate. The extract was then washed with brine, dried over MgSO₄, and
filtered. The solvent was evaporated in vacuo, and the residue subjected to a silica-gel chromatography

Synthesis of terminal functional molecules 23 and 24. Using methylthiomethyl phenyl sulfone
(MP-S) reacted with benzaldehyde and 3-phenylpropionaldehyde in one-pot reaction gave methylthio
aryldiynes 23, 24 in good yield, respectively (Scheme S2). This method is quite simple and does not
require a tedious separation of the reaction mixture. A typical synthetic procedure is as followed: to a
solution of MP-S in THF was orderly added BuLi (1.0 eq), benzaldehyde or 3-phenylpropionaldehyde (1.0
eq), diethyl chlorophosphate ClP(O)(OEt)₂ (1.2 eq), and lithium diisopropylamide (LDA) (2.5 eq). After
the usual workup, the residue subjected to a silica-gel chromatography to give 23 and 24 in 87.5% and
81.5% yield, respectively.

chlorophosphate, lithium diisopropylamide, -78 °C; a) BuLi, 3-(4-iodophenyl)propionaldehyde, diethyl
chlorophosphate, lithium diisopropylamide, -78 °C.

23 and 24: To a solution of MP-S (2.0 mmol) in dry THF (25 mL) was added dropwise BuLi (2.5
M in hexane, 0.8 mL, 2.0 mmol) at -78 °C under nitrogen. The solution was stirred for 10 min. A
solution of 4-iodobenzaldehyde or 3-(4-iodophenyl)propionaldehyde (2.0 mmol) in dry THF (3 mL) was
added dropwise, and the mixture was stirred for 10 min. After diethyl chlorophosphate (2.4 mmol) was added dropwise to the reactant, the cooler was removed. The system was then allowed to warm up to room temperature naturally and stirred for 30 min. The solution was recooled to -78 °C and LDA (5.0 mmol) was added. After stirring for 30 min, the reaction was quenched with saturated NH₄Cl solution. The mixture was diluted with water and extracted with ethyl acetate (30 mL×3). The organic layer was washed (brine), dried (MgSO₄), filtered and evaporated. The residue was purified by silica gel column chromatography.

Determination of enhancement factors:

The SERS enhancement factor (EF) for each of the nanoparticle assemblies was also estimated based on the following relationship:

\[
EF = \frac{I_{\text{sers}}}{I_{\text{raman}}} \cdot \left( \frac{d \cdot \rho_{\text{ligand}} \cdot N_{\text{No}}}{N_{\text{MW}} \cdot \text{ligand/NP}} \right)
\]

\(I_{\text{sers}}\): Raman intensity in the interparticle assembly sample; \(I_{\text{raman}}\): Raman intensity in powder sample, \(d\): diameter of laser beam (\(d = 2 \mu m\)), \(\rho_{\text{ligand}}\): the molecular density of MTAs (1.5 g/cm³), \(N_{\text{No}}\): Avogadro's number, \(N_{\text{MW}}\): molecular weight of MTAs, NPs/cm²: the number of gold nanoparticles per cm², ligand/NP: the number of MTAs per gold nanoparticle in the mediated assembly (V ~ 1.4/NP, Y ~ 0.8/NP, X ~ 1.5/NP, as determined from the UV-Vis data).

Spectrophotometric determination of concentrations and molar absorptivity (ε):

The measurement procedure for the assessment of ligand exchange and replacement in the two-component assemble processes is as follows:

1. After the formation of nanoparticle assembly mediated by the first ligand, the solution was centrifuged and the precipitation was collected.
2. A 6-mL toluene and the second ligand were added into the precipitation, and the solution was then stirred overnight.
(3) For the assembly thus formed, it contained a mixture of the mediator ligands (1st and 2nd).

The number of ligand molecules adsorbed onto the Au nanoparticles was determined by measuring the change of the absorbance for the corresponding bands in Figure 8, from which the change of the concentration of the molecules in the solution before and after the assembly was estimated based on solving the following equations involving the absorbance data for the two mediator molecules:

\[
\begin{aligned}
A_{a(nm)} &= A_{a(nm)}^{1st mediator} + A_{a(nm)}^{2nd mediator} \\
A_{b(nm)} &= A_{b(nm)}^{1st mediator} + A_{b(nm)}^{2nd mediator}
\end{aligned}
\]

\[
\Rightarrow \begin{cases}
A_{a(nm)} = e_{a(nm)}^{1st mediator} \cdot b \cdot c^{1st mediator} + e_{a(nm)}^{2nd mediator} \cdot b \cdot c^{2nd mediator} \\
A_{b(nm)} = e_{b(nm)}^{1st mediator} \cdot b \cdot c^{1st mediator} + e_{b(nm)}^{2nd mediator} \cdot b \cdot c^{2nd mediator}
\end{cases}
\]
