Electrochemical Sensors Based on Porous Nanocomposite Films with Weak Polyelectrolyte-Stabilized Gold Nanoparticles

Sungwoo Kim^a, Yongmin Ko^a and Jinhan Cho^{b,*}

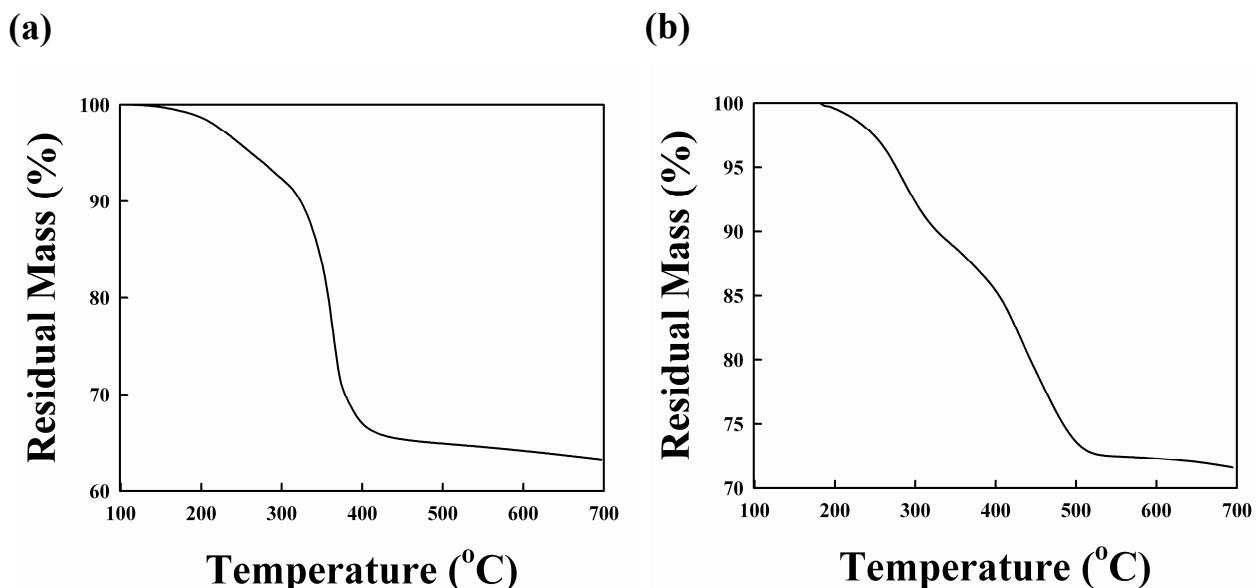

Figure S1. Thermogravimetric analysis of (a) PAA-Au_{NP} and (b) PAA-Au_{NP} powder without excess PAH or PAA chains. For measuring the amount of PEs bound to Au_{NPs}, the powder was annealed with increasing temperature to 700 °C at a heating rate of 5 °C·min⁻¹. After thermal treatment, the amount ratio of thermally decomposed PAH and PAA was measured to be about 36 and 28 %, respectively.

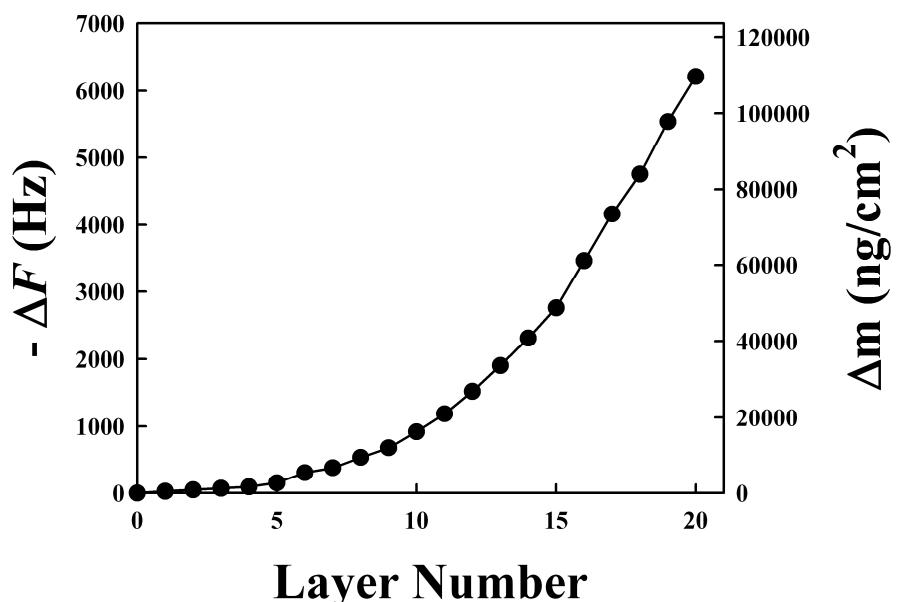

Figure S2. QCM data (i.e., frequency and mass change) of PAH/PAA multilayers as a function of layer number. The solution pH of PAH and PAA were adjusted to 7.5 and 3.5, respectively.

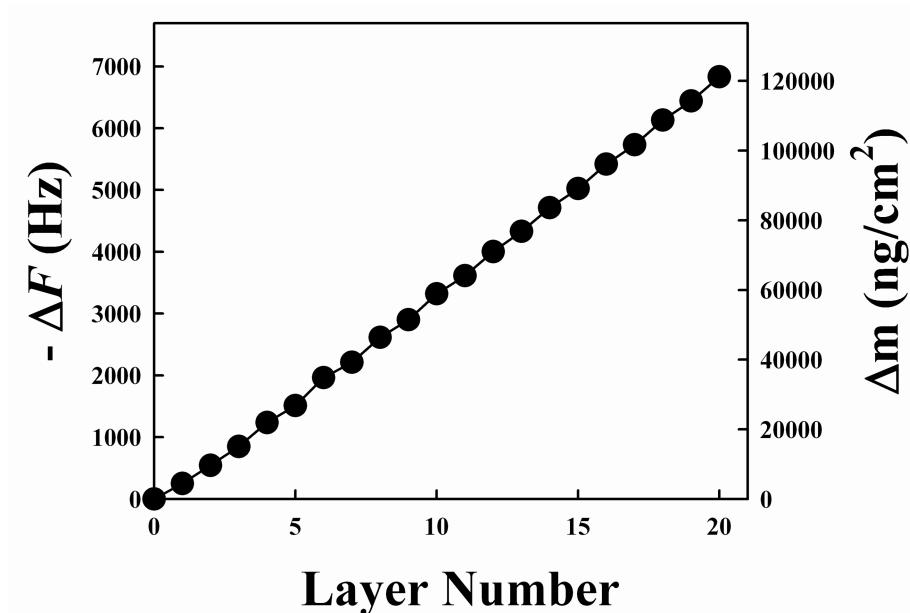

Figure S3. QCM data (i.e., frequency and mass changes) of PAH-Au_{NP}/PAA-Au_{NP} multilayers containing no excess PE chains as a function of layer number. The even and odd layer numbers in QCM data indicate PAA-Au_{NP} and PAH-Au_{NP}, respectively.

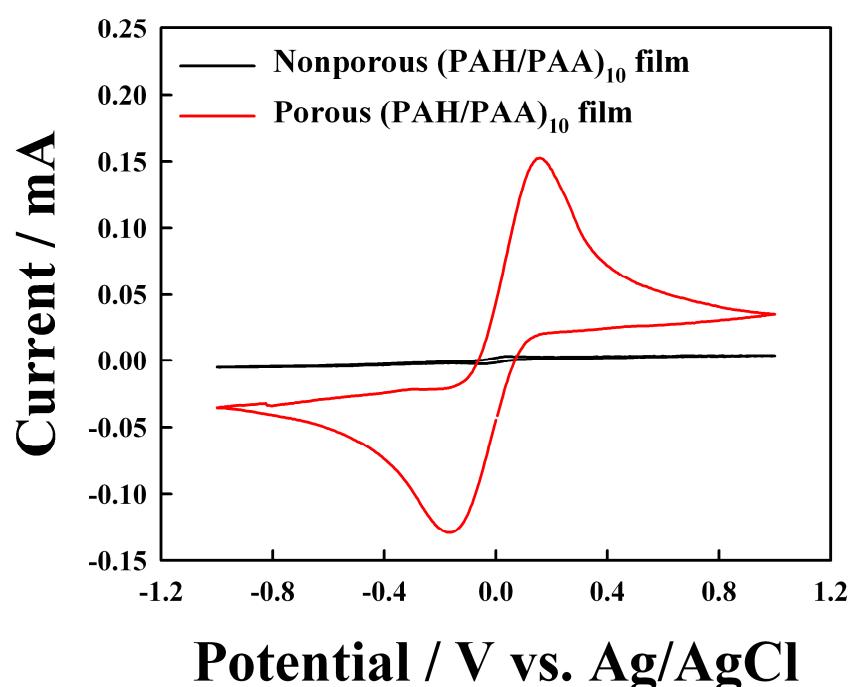

Figure S4. Cyclic voltammograms of 10 mM K₃Fe(CN)₆/K₄Fe(CN)₆ in pH 7.0 PBS at porous and nonporous (PAH-Au_{NP}/PAA-Au_{NP})₁₀ multilayer-coated electrodes with scan rate of 50 mV·S⁻¹.

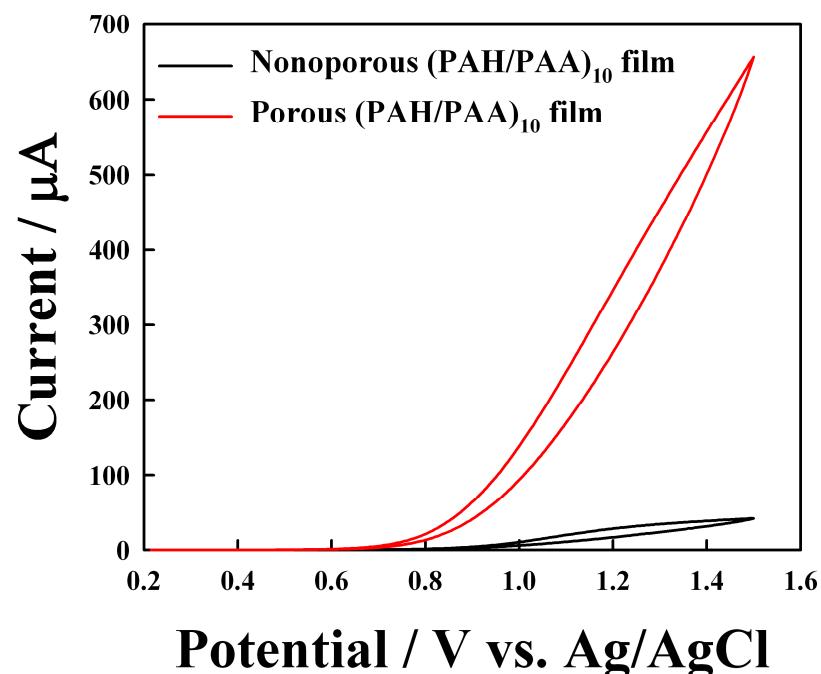

Figure S5. Cyclic voltammograms of the amperometric responses of porous and nonporous $(\text{PAH}/\text{PAA})_{10}$ multilayer-coated electrodes in pH 3.0 PBS containing 20 mM NaNO_2 with scan rate of $50 \text{ mV}\cdot\text{s}^{-1}$.
