The SEM images (Figure S1B, C) showed that the content of NiCl₂ and magnetism filed played the important role to the morphology of Ni NWs. When the concentration of Ni²⁺ decreased, the Ni NWs became the prickly nanostructure. When the external magnetic field increased, the length of the Ni NWs became longer and the prick of the Ni NWs became more. The prickly and the ordered nanostructures were good for the SERS measure. It could form the tip-enhanced Raman spectroscopy which is attributed to the electromagnetic enhancement mechanism.1,2 In the process of SERS measurement, the ordered structure could be assembled in favour of the SERS test. 0.01mL of 10⁻⁵ M R6G solution was dropped on the nanocompositions for the SERS test to verify our conjecture. As shown in the SERS date (Figure 1S I-L), all of the nanostructures have the SERS spectra, and the ordered and assembled Ni/Ag nanocomposition had the strong spectra of R6G. So in the following experiment, the prickly and assembled nanocomposites were used as the SERS substrates.
**Figure S1** SEM images of (A-D) the different morphologic Ni NWs: A) synthesized in the absence of the magnetism filed. Conditions: NiCl$_2$ 5mL N$_2$H$_4$ 1mL non-magnetism B) synthesized in the moderate intensity magnetism. Condition: NiCl$_2$ 5mL N$_2$H$_4$ 1mL. C) synthesized in the moderate in the moderate intensity magnetism. Condition: NiCl$_2$ 0.5mL N$_2$H$_4$ 1mL D) synthesized in the strong-magnetism. Condition: NiCl$_2$ 0.5mL N$_2$H$_4$ 1mL (E-H) Ni/Ag nanocomposites synthesized from the precursor (A-D) by adding 10mL AgNO$_3$(1M). I-L are the SERS data obtain from the different morphologic nanocomposites.
