Chemistry

General

All solvents were distilled prior to use; anhydrous solvents and reagents were distilled under N₂. EtOH was dried over 4Å molecular sieves. THF and Et₂O for organometallic reactions were distilled from sodium benzophenone ketyl. THF for reductive amination was dried over 4Å sieves. Petrol denotes the hydrocarbon fraction distilling from 64–67 °C. Acid chlorides were distilled under N₂ prior to use. All reaction temperatures refer to bath temperatures. Organic extracts were dried over anhydrous MgSO₄ and then filtered. Solvents were evaporated under vacuum or under a stream of N₂.

Rapid silica filtration refers to chromatography on a short column of silica (BDH, for flash chromatography, 40–63 μm) in a sintered glass funnel, in which the eluent is sucked through the column under vacuum. Analytical TLC was performed on Whatman flexible plates (250 μm layer, Al Sil G/UV254). Spots were visualised under UV light and by staining with acidified 2,6-dinitrophenylhydrazine (ketones) or ninhydrin (amines). Gas chromatography-mass spectrometry (GC-MS) was conducted on a Shimadzu GCMS QP-2010 equipped with a RESTEK RTX-5MS 30 m × 0.25 mm ID × 0.1 μm df, or a RESTEK Stabilwax 30 m × 0.23 mm ID × 0.1 μm df column, in positive ionisation mode using electron impact ionisation (EI).

Melting points were measured on a Kofler hot stage melting point apparatus and are uncorrected. Microanalyses were conducted by The Australian National University Research School of Chemistry Microanalysis Unit or by Robertson Microlit. Electrospray mass spectra were acquired from methanolic solutions on a VG Autospec or VG Micromass 7070F double focusing mass spectrometer in positive ionisation mode. Low resolution electron impact mass spectra were acquired on a Shimadzu GC–MS QP-2010 gas chromatograph-mass spectrometer in positive ionisation mode. High resolution mass spectra were acquired on a VG-Autospec mass spectrometer using fast atom bombardment (FAB) or electron impact ionisation (EI). NMR spectra were acquired on Varian Gemini 2 (300 MHz, ¹H; 75.5 MHz, ¹³C), Bruker AM-300 (300 MHz, ¹H; 75.5 MHz, ¹³C), Varian Inova 300 (300 MHz, ¹H; 75.5 MHz, ¹³C), Varian 400 (400 MHz, ¹H; 100 MHz, ¹³C), Bruker Avance 500 (500 MHz, ¹H; 125 MHz, ¹³C) or Bruker AV600 (600 MHz, ¹H; 150.9 MHz, ¹³C) spectrometers, as indicated. All spectra were recorded in CDCl₃ unless otherwise indicated. Chemical shifts are expressed in ppm, relative to CHCl₃ (¹H, 7.26 ppm), CDCl₃ (¹³C, 77.0 ppm), CD₃SOCD₂H (¹H, 2.50 ppm), CD₃COCD₂H (¹H, 2.05
ppm) or CD$_3$COCD$_3$ (13C, 29.8 ppm), as appropriate. Routine assignments of 13C NMR spectra were made with the assistance of DEPT 135 and DEPT 90 experiments.

Purity (>95%) of target amine hydrochlorides was established by elemental analysis:

Synthesis

Piperonylmagnesium chloride (6). Magnesium turnings (20.0 g, 0.823 mol) were stirred under a stream of N₂ for 7 d during which time a black powder accompanied by a magnesium mirror formed. Anhydrous Et₂O (100 mL) was added and the suspension was cooled to 0 °C. A solution of piperonyl chloride² (13.753 g, 80.62 mmol) in anhydrous Et₂O (200 mL) was added dropwise to the vigorously stirred suspension over 3 h. Stirring was continued and the formation of the Grignard reagent was monitored by disappearance of piperonyl chloride in the GC–MS of a hydrolysed sample (aq. NH₄Cl, Et₂O). After 2 h the chloride was consumed and the suspension was filtered through a glass frit via cannula. The concentration of the Grignard reagent 6 in the filtrate was determined by titration³ to be 0.20 M (74%). The Grignard has a half life of 7 d when stored at −22 °C under a positive pressure of N₂. Replacing Et₂O with THF gave similar yields.

Addition of piperonylmagnesium chloride (6) to nitriles

1-(1,3-Benzodioxol-5-yl)pentan-2-one (7c) (Method A). A 0.27 M solution of piperonylmagnesium chloride in anhydrous Et₂O (9.0 mL, 2.43 mmol) was added to a stirred solution of butyronitrile (0.20 mL, 2.29 mmol) in anhydrous Et₂O (10 mL). The reaction mixture was heated under reflux and monitored by GC–MS (NH₄Cl, Et₂O mini-workup). After 1 h the Grignard reagent had been consumed and the mixture was cooled to room temperature. Ice-water (30 mL) was added, followed by 2 M HCl (30 mL) and the flask was left to stir at room temperature overnight. The phases were separated and the aqueous phase was extracted with Et₂O (3 × 30 mL). The combined organic phase was washed with saturated NaHCO₃ solution (30 mL), water (30 mL) and brine (30 mL), then dried and evaporated to give a colourless oil (509 mg), which was subjected to rapid silica filtration. Elution with 1:19 EtOAc/petrol gave 7c as colourless oil (134 mg, 29%), identical with the material described below.
2-(1,3-Benzodioxol-5-yl)-1-phenylethanone (7g) (Method A). Benzonitrile (3.1 mL, 30 mmol) was added to a stirred, 0.2 M solution of piperonylmagnesium chloride in anhydrous THF (180 mL, 36 mmol) under N₂. The reaction mixture was heated under reflux for 24 h, after which time TLC indicated the complete consumption of benzonitrile. The reaction was cooled to room temperature and quenched with cold 0.5 M HCl (100 mL), upon which a white precipitate immediately formed. After stirring for 20 minutes, the phases were separated and the aqueous phase was extracted with Et₂O (3 × 100 mL). The extract was washed with brine (100 mL), dried and concentrated to give a brown residue (8.87 g), which was purified by flash chromatography. Elution with 1:1:18 EtOAc/toluene/petrol gave 7g as pale yellow solid (5.76 g, 80%), identical with the material described below.

Piperonylcuprate (8). A 0.20 M solution of piperonylmagnesium chloride (480 mL, 96 mmol) in anhydrous Et₂O was transferred via cannula into a solution of CuCN (8.68 g, 96.9 mmol) and anhydrous LiCl (8.32 g, 197 mmol) in anhydrous THF (480 mL) at −78 °C under N₂, whereupon the yellow solution turned red. After stirring at −78 °C for 5 min a yellow precipitate formed, which dissolved upon warming to −45 °C. The solution of the organocuprate thus prepared was used directly in the synthesis of ketones 11b–11g.

For the synthesis of ketones 11h–11t, calculations were based on 100% conversion of piperonyl chloride into organocuprate 8, as described above. The actual conversion is somewhat lower, thus the yields 11h–11t below are lower estimates.

**Representative procedure for the synthesis of piperonyl ketones from 8**

1-(1,3-Benzodioxol-5-yl)pentan-2-one (7c). Butyryl chloride (1.00 mL, 9.70 mmol) was added to a suspension of the bright yellow organocuprate 8 (100.0 mL, 10.0 mmol) at −78 °C. The reaction mixture was allowed to slowly warm to 0 °C over 2 h, during which time a red/brown precipitate
formed. The reaction mixture was poured onto ice cold 0.1 M HCl (100 mL) and the resulting white precipitate was filtered off. The phases in the filtrate were separated and the aqueous phase was extracted with Et₂O (3 × 30 mL). The combined organic phase was washed with water (30 mL), brine (30 mL), dried and evaporated to give a yellow oil, which was purified by rapid silica filtration. Elution with 1:19 EtOAc/petrol gave 7c as an off-white oil (1.692 g, 85%). R_f (1:4 EtOAc/petrol): 0.4. \[\text{1-(1,3-benzodioxol-5-yl)-3-phenylpropan-2-one (7p).}\]

A 1.57 M solution of BuLi in hexanes (3.95 mL, 6.20 mmol) was added to a stirred solution of 9 (1.38 g, 5.91 mmol) in anhydrous THF (20 mL) at –78 °C under Ar. After stirring with the exclusion of light for 30 min, benzyl bromide (772 \(\mu\)L, 6.50 mmol) was added and the resulting mixture was allowed to warm to room temperature over 4 h. A saturated aqueous solution of NH\(_4\)Cl (20 mL) was added, followed by extraction with Et\(_2\)O (3 × 10 mL). The extract was washed with water (2 × 10 mL) and brine (10 mL), dried and evaporated to give the crude diazene intermediate as a yellow oil. This was dissolved in cold 1:1 TFA/H\(_2\)O (2 mL) and stirred at room temperature with the exclusion of light for 3 h. The reaction mixture was diluted with water (50 mL) and extracted with Et\(_2\)O (3 × 25 mL). The extract was washed with portions of 5 M NaOH (5 mL until basic), water (2 × 25 mL) and brine (25 mL), dried and evaporated to give a dark oil, which was adsorbed onto Celite and subjected to flash column chromatography. Elution with 1:49–1:19 EtOAc/hexanes gave 7p as a pale yellow oil which solidified upon standing (452 mg, 36%), mp 56–58 °C. [lit.\(^\text{11}\) 91–92 °C]. \(R_f\) (1:4 EtOAc/petrol): 0.50. 1,3-bis(1,3-benzodioxol-5-yl)propan-2-one (dipiperonyl ketone) (7q). A solution of homopiperonylic acid 10 (1.80 g, 10.0 mmol) in anhydrous DCM (30 mL) was added to a stirred solution of DMAP (0.34 g, 2.78 mmol) and DCC (2.07 g, 10.0 mmol) in anhydrous DCM (20 mL) under N₂. The resulting orange solution was stirred for 24 h during which time a colourless precipitate formed. The suspension was filtered through a short column of Celite and washed through with DCM. The filtrate was concentrated under vacuum to yield an amorphous orange solid which was subjected to flash chromatography. Elution with 1:10:89 toluene/EtOAc/petrol gave a yellow solid which crystallised from ethanol to afford 7q as off-white needles (0.75 g, 50 %), mp 85–86 °C [lit.¹³ 79 °C]. Biological Assays

Anti-proliferative actions against a Burkitt's lymphoma cell line

The L3055 cell line is derived from a patient with sporadic-type Epstein-Barr virus-negative Burkitt’s lymphoma and is maintained in culture at “early passage” by resurrecting ampoules frozen between passage 8–15 and reculturing for no more than 75 passages in total. Such cells retain their “biopsy phenotype” including sensitivity to pro-apoptotic signals such as provided by MDMA. Cells are cultured at 37 °C in RPMI 1640 supplemented with 10% prescreened and heat-inactivated fetal calf serum, 2 mM L-glutamine and antibiotics. Cytotoxicity was measured by staining of treated cells with
propidium iodide (PI). PI is an impermeable fluorescent dye which binds to double-stranded DNA, therefore PI stains only dead, not live cells. Cells cultured for 24 h ± compound as detailed in ref. 16 were collected in FACS polystyrene tubes and diluted with FACS buffer and kept on ice. PI at a final concentration of 0.85 μg/mL or 1.15 μg/mL was added prior to the FACS readout. For each sample 4000–10000 events were taken consistently within each experiment. Data were fitted to a four-parameter logistic equation using the iterative curve-fitting program, Kaleidagraph.

**Neuroblastoma toxicity assays**

Human dopaminergic neuroblastoma SH-SY5Y cells (ATCC) (P10 to P30) were cultured in Dulbecco’s Modified Eagle’s Medium (DMEM) (6.4 g/L NaCl, 3.7 g/L NaHCO3, 400 mg/L KCl, and 584 mg/L L-glutamine) supplemented with 5% bovine calf serum in a sterile humidified chamber (37 °C, 95% CO2, 5% O2) until confluent. Cells were passed using 0.1% trypsin for 5 min, then pelleted by centrifuging at 1400 rpm. Twenty four hours following addition to 96 well plates, cells were incubated with concentration response curves (1–600 μM) of MDMA (1), 11g, 11r or 11s. Media was used as vehicle for all four compounds. The redox sensitive dye Alamar Blue (0.4% of final volume) was added immediately following addition of the compounds, and cells were incubated for 24 hours. Cell viability was assessed by measuring the change in fluorescence of Alamar Blue (ex. 544nm, em. 590nm) using a FLUOstar OPTIMA. n = 6, where each n is the mean of six replicates. Data were analysed using ANOVA followed by Dunnett’s multiple comparison’s test.

**Prepulse Inhibition Studies**

Male Wistar rats (72) were assigned to one of three groups (MDMA, PMA and 11g) and tested with four doses (4.4, 8.8, 44 and 88 μmol/kg) in a randomised, Latin square within-subjects design. Testing with saline vehicle was conducted before and after testing with drugs and the results of these two test days averaged to give vehicle control values.

The PPI testing procedure has been described previously. 18 Briefly, animals were pretreated with the appropriate drug and placed into Med Associates (St Albans, VT) startle chambers. White noise (70 dB) background was played throughout the test session. White noise startling stimuli (40 ms duration) of 70–120 dB in 5 dB increments were presented in every possible combination randomly with 10 ms white noise prepulse stimuli (70–95 dB in 5 dB increments) which preceded the startling stimuli by 50 ms. Stimulus intensity-response magnitude curves were fitted to the data as described previously 18 and
prepulse inhibition calculated using $100\times \left( \frac{R_{\text{MAX pulse alone}} - R_{\text{MAX prepulse+pulse}}}{R_{\text{MAX pulse alone}}} \right)$, where $R_{\text{MAX}}$ = the maximum response achievable from a subject under a given drug and prepulse condition.

**Receptor/Transporter Binding protocol**

**Tissue preparation**
Female Sprague-Dawley rats (250 g) were killed by decapitation following CO$_2$ narcosis. Brains were immediately removed and placed into ice-cold Krebs’ buffer (134 mM NaCl, 5 mM KCl, 1.3 mM CaCl$_2$, 1 mM MgSO$_4$, 25 mM NaHCO$_3$, 1.25 mM KH$_2$PO$_4$, and 10 mM glucose). Various brain regions (cerebral cortex, striatum, cerebellum and remaining brain) were dissected out and placed separately into ice-cold Tris buffer (pH 7.4) prior to sonication. Brain homogenates were then centrifuged for 20 min (4 °C, 20,000 rcf), resuspended and spun again. Following centrifugation, supernatant was removed, and the pellet resuspended, vortexed and placed in a 37 °C water bath for 20 min. Following a final centrifugation step supernatant was removed and the pellet re-suspended. Protein concentration was determined by a variant of the Folin’s phenol reagent method described by Lowry et al.$^{19}$

**Homogenate binding - Radioligands and drugs**

**Receptor and transporter binding assays**
An initial receptor binding screen was employed in which the ability of a single 10 µM concentration of compound to displace at least 50% of specific binding was assessed. Compounds which failed to reach this threshold were not subjected to full profiling at that site. The reactions were conducted using 380 µL 96-well plates. For full dose-effect assays, concentrations of 1 mM, 300 µM, 100 µM, 30 µM, 10 µM, 1 µM, 300 nM, 100 nM, 30 nM, 10 nM, 1 nM of drug were incubated in the presence of the radioligand with and without non-specific displacer and brain homogenate. Binding conditions relating to brain region used, ligand and ion concentration as well as incubation conditions employed for each of the assays are shown below.

After incubation, the membranes were rapidly washed in 50 mM Tris buffer (20 sec wash at 10 mL/sec) and filtered under vacuum through glass fibre filters using a cell harvester. For SERT and DAT assays, filters were pre-soaked in a 50 mM Tris (pH 7.4) solution containing 0.1% polyethyleneimine and with 0.1% bovine serum albumin added to the filtration buffer. Filters were then dissolved in scintillation fluid and radioactivity determined with a scintillation counter.
Statistical analysis
Following removal of the outliers, values of three triplicate experiments were averaged, and expressed as a percentage of total displacement. Dose-response curves were constructed and the half maximal inhibitory concentration (IC$_{50}$) determined via non-linear regression analysis (GraphPad Prism 5.02, GraphPad Software Inc, La Jolla, CA, USA). The inhibition constant ($K_i$) was calculated using the Cheng-Prusoff equation.$^{20}$
