S1. General Experimental

All reagents were purchased from Aldrich, Fluka or Lancaster and used without further purification. DNA phosphoramidite monomers, solid supports and additional reagents were purchased from Link Technologies Ltd, Glen Research or Applied Biosystems Ltd. Dichloromethane (DCM), acetonitrile (CH₃CN), N,N-diisopropylethylamine (DIPEA), triethylamine (Et₃N) and pyridine were distilled over calcium hydride. All reactions were carried out under an argon atmosphere using glassware that had been dried at 120°C overnight. Column chromatography was carried out under pressure using Fisher scientific DAVSIL 60A 30-70 micron silica. Thin layer chromatography (TLC) was performed using Merck Kieselgel 60 F₂₅₄ (0.22mm thickness, aluminium backed). Compounds were visualized at 254 nm or stained with 10% sulfuric acid in EtOH or 2.5% p-anisaldehyde in EtOH solution (EtOH:H₂O = 95:5, containing 3.4% conc. sulfuric acid and 1% acetic acid).

¹H-NMR spectra were measured at 300 MHz on a Bruker AV 300 spectrometer or 400 MHz on a Bruker DPX 400 spectrometer. ¹³C-NMR spectra were measured at 75 MHz or 100 MHz on the same spectrometers. Chemical shifts are given in ppm and J values are given in Hz. All assignments for ¹H-NMR and ¹³C-NMR have been confirmed by H-H COSY, HMQC and HMBC. ³¹P NMR spectra were recorded on a Bruker AV 300 spectrometer at 121 MHz. MeOD-d⁴, MeCN-d₃, CDCl₃ and DMSO-d⁶ were used as solvents. The IR spectra were obtained on ThermoNicolet 380 FT-IR spectrometer with Smart Orbit Goldengate attachment. Low resolution mass spectra were recorded in acetonitrile or methanol using the electrospray technique on a Fisons VG platform instrument. High resolution mass spectra were recorded in acetonitrile or methanol using the electrospray technique on a Bruker APEX III FT-ICR mass spectrometer. HPLC grade of MeOH or CH₃CN was used as solvents.

**Bis-N,N-(4-Methoxybenzyl)amino]-3-methyl-5-bromopyridine (2)**

2-Amino-3-methyl-5-bromopyridine (50.5 g, 270 mmol) was dissolved in anhydrous DMF (500 ml) to which 4-methoxybenzyl chloride (100 mL, 737 mmol) was added. The solution was cooled to 0 °C before adding NaH in portions (60% dispersed in mineral oil, 29.5 g, 737 mmol). The reaction mixture was stirred at rt for 8 h after which methanol (20 mL) was added and the resulting solution was partitioned between DCM (400 mL) and water (200 mL). The organic layer was separated and the aqueous layer further extracted with DCM (200 mL × 2). The organic layers were combined and washed by water (200 mL × 3), saturated sodium bicarbonate (200 mL × 1), water (200 mL × 1) and brine (200 mL × 1). After being dried over anhydrous sodium sulfate, the solution was evaporated *in vacuo* to give an orange coloured oil. After recrystallisation (95% ethanol), a white solid 2 was obtained (70.0 g, 61%).

A solution of 3¹ (5.00 g, 14.5 mmol) in anhydrous DMF (60 ml) was cooled to 0 °C and NaH was added (60% dispersion in mineral oil, 0.87 g, 21.7 mmol). The mixture was stirred at 0 °C for 1 h before iodomethane (1.81 mL, 29.1 mmol) was added dropwise. The suspension was stirred at rt for 8 h. Upon completion, water (5 mL) was added. After the solvents were removed in *vacuo*, the residue was redissolved in DCM (100 mL) and washed with water (50 mL × 3), dilute hydrochloric acid (0.5%, 50 mL × 1), saturated sodium bicarbonate (50 mL × 1), water (50 mL × 1) and brine (50 mL × 1). After being dried over anhydrous sodium sulfate, the solution was evaporated *in vacuo* to remove the solvent and the residue was
purified by silica gel column chromatography (30% ethyl acetate in petroleum ether) to give the product as pale yellow oil (3.80 g, 73%). 2-[N-(4-Methoxybenzyl)amino]-3-methyl-5-(2’-O-methyl-3’,5’-di-O-benzyl-\beta-D-ribofuranosyl)-pyridine (8a)

Compound 7a (1.96 g, 2.84 mmol) was dissolved in anhydrous DCM (20 mL) and cooled to -78 °C under an argon atmosphere before adding triethylsilane (1.40 mL, 8.76 mmol) and boron trifluoride diethyl etherate (1.08 mL, 8.75 mmol). The mixture was left to stir at -78 °C for 4 h then left at rt for 16 h. Saturated sodium bicarbonate (120 mL) was added to quench the reaction and the mixture was further stirred for 1 h. The mixture was then extracted by DCM (60 mL \times 3) and the organic layers were combined and washed by water (60 mL \times 3), saturated sodium bicarbonate (60 mL \times 1), water (60 mL \times 1) and brine (60 mL \times 1). After being dried over anhydrous sodium sulfate, the solution was evaporated \textit{in vacuo} to remove solvent and the residue was purified by silica gel column chromatography (40% ethyl acetate in petroleum ether) to give the product as amber gum (1.43 g, 91%). Compound 7b (6.06 g, 8.25 mmol) was dissolved in anhydrous DCM (100 mL) and cooled to -78 °C under an argon atmosphere before adding triethylsilane (7.90 mL, 49.4 mmol) and boron trifluoride diethyl etherate (6.10 mL, 49.4 mmol). The mixture was left to stir at -78°C for 4h then left at rt for 16 h. Saturated sodium bicarbonate (150 mL) was added to quench
the reaction and the mixture was further stirred for 1 h then extracted with DCM (100 mL × 3). The organic layers were combined and washed by water (100 mL × 3), saturated sodium bicarbonate (100 mL × 1), water (100 mL × 1) and brine (100 mL × 1). After being dried over anhydrous sodium sulfate, the solution was evaporated in vacuo to give the crude product as amber oil (10.0 g), which was used in the next reaction without further purification. **S5. Oligonucleotide synthesis purification and analysis**

Oligonucleotide synthesis was carried out on an Applied Biosystems 394 automated DNA/RNA synthesizer using a standard 0.2 µmol or 1.0 µmol phosphoramidite cycle of acid-catalyzed detritylation, coupling, capping, and iodine oxidation. The capping step was omitted when N2-trifluoroacetyl-protected MAP phosphoramidites were incorporated. All 2-cyanoethyl phosphoramidite monomers were dissolved in anhydrous CH\(_3\)CN to a
concentration of 0.1 M immediately prior to use. The coupling time for normal A, G, C, and T monomers was 30 s and this was extended to 6 min for all modified monomers. Stepwise coupling efficiencies and overall yields were determined by automated trityl cation conductivity monitoring and in all cases were > 98.0%. The oligonucleotides attached to the synthesis columns were treated with 20% diethylamine in acetonitrile for 20 min then washed with acetonitrile (5 x 1mL). This procedure removes cyanoethyl groups from the phosphotriesters and scavenges the resultant acrylonitrile, preventing cyanoethyl adducts being formed at the primary amines of MAP or at the amino group of 2’-aminoethoxy-5-methyl-uridine. After this, cleavage of oligonucleotides from the solid support and deprotection were achieved by exposure to concentrated aqueous ammonia for 12 h at room temperature. Purification of oligonucleotides was carried out by reversed-phase HPLC on a Gilson system using a Brownlee Aquapore column (C8, 8 mm x 250 mm, 300 Å pore) with a gradient of CH3CN in NH4OAc increasing from 0% to 100% buffer B over 30 min with a flow rate of 4 mL/min (buffer A: 0.1 M NH4OAc, pH 7.0; buffer B: 0.1 M NH4OAc with 50% CH3CN, pH 7.0). Elution of oligonucleotides was monitored by ultraviolet absorption at 298 nm. After HPLC purification, oligonucleotides were desalted using NAP-10 Sephadex columns (GE Healthcare) according to the manufacturer’s instructions.

TFOs were analysed by negative mode electrospray MS on a Fisons VG platform spectrometer in water with triisopropylamine (0.02%). Hairpin duplexes were analysed by MALDI-TOF using a ThermoBioAnalysis Dynamo MALDI-TOF spectrometer in positive ion mode. The mass data can be found in Table S1.

S6. Ultraviolet triplex melting studies

To determine triplex melting temperatures (Tm), UV melting studies were carried out on a Varian Cary 400 scan UV-visible spectrophotometer using Hellma SUPRASIL synthetic quartz 10 mm path length cuvettes, monitoring at 280 nm with a DNA duplex concentration of 1.0 μM and a volume of 1.2 mL. Samples were prepared as follows: The third strand and
the duplex were mixed in a 3:1 ratio in 2 mL Eppendorf tubes then lyophilized before suspending in 1.2 mL of the appropriate buffer solution (10 mM sodium acetate with 2mM spermine containing 200 mM NaCl, pH 5.5; 10 mM sodium acetate, pH 5.5 containing 200 mM NaCl or 10 mM sodium phosphate, pH 6.2, 6.6, 7.0, 7.5 or 8.0 containing 200 mM NaCl). The samples were then filtered into the cuvettes with Kinesis regenerated cellulose 13 mm, 0.45 μm syringe filters. The UV melting protocol involved initial denaturation by heating to 80 °C at 10 °C /min followed by annealing by cooling to 15 °C at 0.5 °C /min, then maintaining at 15 °C for 20 min before starting the melting experiment which involved heating from 15 °C to 80 °C at 0.5 °C /min, holding at 80 °C for two min then cooling to 15 °C at 0.5 °C /min. At least two successive melting curves were measured. The $T_m$ values were calculated using Cary Win UV thermal application software, taking an average of the melting curves.

**S7. Ultraviolet duplex melting studies**

To determine duplex melting temperatures UV melting studies were carried out at 260 nm with a complementary single DNA strand concentration of 1.0 μM and a volume of 1.2 mL. Samples were prepared as follows: The TFO and the single-stranded DNA were mixed in a 1.00:1.05 ratio in 2 mL Eppendorf tubes then lyophilized before dissolving in 1.2 mL of sodium phosphate, pH 7.0 containing 200 mM NaCl. The samples were then filtered into the cuvettes with Kinesis regenerated cellulose 13 mm, 0.45 μm syringe filters. The UV melting protocol involved initial denaturation by heating to 84 °C at 10 °C /min followed by annealing by cooling to 12 °C at 1.0 °C /min, then maintaining at 12 °C for 20 min before starting the melting experiment which involved heating from 12 °C to 84 °C at 1.0 °C /min, holding at 84 °C for two min then cooling to 12 °C at 1.0 °C /min. Three successive melting curves were measured. The $T_m$ values were calculated using Cary Win UV thermal application software, taking an average of the three melting curves.

**S8. DNase I footprinting**

The target sequence for the DNase I footprinting experiments with the TFOs was prepared by
ligating the sequence
5’-GATCAAAAACAAGCAGGAGGAAAAAAGCAACTGTATGC (TFO target site underlined) into the BamHI site of pUC19. The resulting clone contained a dimer of this sequence with the two copies oriented in opposite directions, enabling simultaneous visualization of the pyrimidine (lower site) and purine (upper site) strands. The radiolabelled footprinting fragment was prepared by digesting the plasmid with EcoRI and HindIII and labeling the insert at the 3’-end of the EcoRI site with α-[32P]-dATP using reverse transcriptase. DNase I digestion was performed as previously described. Radiolabelled DNA (1.5 µL) was incubated overnight with 3 µL oligonucleotide (dissolved in 50 mM sodium acetate pH 5.0 containing 2.5 mM MgCl2). Samples were digested with DNase I (0.01 units/mL, dissolved in 20 mM NaCl, 2 mM MgCl2, 2 mM MnCl2) for 2 minutes before stopping the reaction by adding 4 µL of formamide containing 10 mM EDTA. The products of the reaction were separated on 10% polyacrylamide gels containing 8M urea. The gel was fixed, dried and exposed to a phosphorimager screen overnight.

S9. Serum stability studies
Oligonucleotides TFO-16, TFO-17, TFO-18 or TFO-19 (1.4 OD260) were freeze-dried and dissolved in sodium phosphate buffer (80 µl, 10 mM phosphate, pH 7.0, 200 mM NaCl). A 10 µl aliquot from this solution was removed, mixed with 5 µl of the same buffer and used as a negative control. Fetal bovine serum (10.5 µl) and sodium phosphate buffer (24.5 µl, 10 mM phosphate, pH 7.0, 200 mM NaCl) were added into the remaining 70 µl of the solution, which was then vortexed and incubated at 37 °C. At each time point (1h, 3h, 6h, 12h and 24h) 15 µl was taken and stored in a freezer at -20 °C until all the samples were collected. Formamide (15 µl) was added to each sample and all were vortexed, heated at 80 °C for 5min and cooled in ice before loaded on a denaturing 20% polyacrylamide gel for electrophresis. The gels were visualized in “epi short wave UV” mode by Genesnap software V7.08 on Syngene G-Box gel imager.
X-ray crystallography

X-ray Data were collected on a Bruker Nonius KappaCCD with a Mo rotating anode generator and standard data collection and processing procedures were followed. Absolute structures were not determined experimentally but inferred from the synthetic procedures.

The final $R_1$ values were 0.0342 ($I>2\sigma(I)$). The final $wR(F_2)$ values were 0.0720 ($I>2\sigma(I)$). The final $R_1$ values were 0.0383 (all data). The final $wR(F_2)$ values were 0.0747 (all data).

Crystal data for 2-[N-(phenoxyacetyl)amino]-5-(2’-deoxy-β-D-ribofuranosyl)pyridine (14)

$M = 344.36$, Monoclinic, $a = 10.1283(3)$, $b = 8.5022(3)$, $c = 11.0211(4)$ Å, $\beta = 117.1590(10)^\circ$, $U = 844.42(5)$ Å$^3$, $T = 120(2)$ K, space group $P21$, $Z = 2$, 8823 reflections measured, 1594 unique reflections ($R_{int} = 0.1598$). The final $R_1$ values were 0.0461 ($I>2\sigma(I)$). The final $wR(F_2)$ values were 0.1109 ($I>2\sigma(I)$). The final $R_1$ values were 0.0515 (all data). The final $wR(F_2)$ values were 0.1152 (all data).
**Figure S1.** UV melting curves (left) and derivatives (right) of TFO-1, TFO-2, TFO-3, TFO-6, TFO-7, TFO-8 with the corresponding target hairpin duplexes. A) TFO-1 (green), TFO-2 (red) and TFO-3 (black) at pH 5.5 containing 2mM spermine; B) TFO-1 (green), TFO-2 (red) and TFO-3 (black) at pH 5.5; C) TFO-6 (green), TFO-7 (red) and TFO-8 (black) at pH 5.5 containing 2mM spermine; D) TFO-6 (green), TFO-7 (red) and TFO-8 (black) at pH 5.5. Experiments were performed in 10 mM sodium acetate pH 5.5 containing 200 mM NaCl (with or without 2 mM spermine). The concentration ratio of TFOs/target duplex was 3.0 μM:1.0 μM for UV melting.
Figure S2. UV melting curves (left) and derivatives (right) of TFO-3, TFO-4, TFO-5, TFO-8, TFO-9, TFO-10, TFO-13, TFO-14 and TFO-15 with the corresponding target hairpin duplexes. A) TFO-3 (black), TFO-4 (red) and TFO-5 (green) at pH 7.0; B) TFO-8 (black), TFO-9 (red) and TFO-10 (green) at pH 7.0; C) TFO-13 (black), TFO-14 (red) and TFO-15 (green) at pH 7.0. Experiments were performed in 10 mM sodium phosphate pH 7.0 containing 200 mM NaCl. The concentration ratio of TFOs/target duplex was 3.0 µM:1.0 µM for UV melting.

Figure S3. UV melting curves (left) and derivatives (right) of TFO-11-15 with their Watson-Crick complementary single strand DNA at pH 7.0: TFO-11 (green), TFO-12 (red), TFO-13 (black), TFO-14 (yellow), TFO-15 (blue). Experiments were performed in 10 mM sodium phosphate pH 7.0 containing 200 mM NaCl. The concentration ratio of TFOs/single strand DNA was 1.00 µM:1.05 µM for UV melting.

Mass spectra of triplex forming oligonucleotides (TFOs) were recorded by negative mode electrospray on a Fisons VG platform spectrometer in water with triisopropylamine (2µL of 1% solution in MeOH). Hairpin duplexes were analysed by MALDI-TOF using a ThermoBioAnalysis Dynamo MALDI-TOF spectrometer in positive ion mode with oligo-dT as reference.
