Experimental Procedures

Chemistry

General. All chemicals were used as received from the manufacturer (Aldrich Chemicals and Fisher Scientific) and all reactions were carried out under a nitrogen or argon atmosphere. All solvents were dried over 4 Å molecular sieves prior to their use. NMR spectra were obtained on either a Bruker 300 MHz spectrometer or a Bruker 500 MHz spectrometer in CDCl₃, d₆-DMSO or d₆-acetone solutions. IR spectra were recorded on a Nicolet Avatar 320 FT-IR spectrometer with an HATR attachment. High-resolution mass spectra were provided on a Biotof Q electrospray mass spectrometer at the University of Richmond or an AxION 2 time of flight mass spectrometer at Virginia Commonwealth University. Low-resolution MS spectra were obtained on a Shimadzu QP 5050 instrument. Melting points and boiling points are uncorrected. Flash chromatographic separations were carried out on a Biotage SP-1 instrument, which was equipped with a silica cartridge, and ethyl acetate/hexane used as the eluant. Microwave accelerated reactions were carried out in a Biotage Initiator system. Microwave reactions were controlled at a constant temperature whereby the microwave power was allowed to fluctuate so as to maintain a constant temperature and safe pressure limits. TLC analyses were conducted on silica plates with hexane/ethyl acetate as the eluant. Vinamidinium salts utilized for pyrrole formation were prepared according to standard procedures. All purified reaction products gave TLC results, MS spectra, flash chromatograms and ¹³C NMR spectra consistent with a sample purity of >95%. Scheme 1 depicts Method A and Method B, which were used for the preparation of the pyrrole analogs with one exception. Compound 5q was prepared by bromination of compound 2 with dibromdimethylhydantoin as indicated in the experimental procedures that follow.

**Biological Activity**

**Cell Culture.** The MDA-MB-435 human melanoma cancer cell line was obtained from the Lombardi Cancer Center (Georgetown University; Washington, DC) and grown in Richter’s IMEM medium (Invitrogen; Carlsbad, CA) supplemented with 10% fetal bovine serum (Hyclone; Logan, UT) and 25 μg/mL gentamicin sulfate (Invitrogen). The A-10 embryonic rat aortic smooth muscle cell line was purchased from American Type Culture Collection (Manassas, VA) and
cultured in Basal Medium Eagle medium (Sigma; St. Louis, MO) with 10% fetal bovine serum and 50 μg/mL gentamicin sulfate.

**Inhibition of Cellular Proliferation.** Antiproliferative effects were evaluated using the SRB assay\(^5^5\) as previously described.\(^5^6\) The concentration of drug that caused a 50% inhibition of cellular proliferation (IC\(_{50}\)) was calculated from the linear portion of the log of the dose response curve. Each IC\(_{50}\) represents the mean and standard deviation from three independent experiments, each performed in triplicate. Colchicine is included as a reference compound.

**Immunofluorescence.** Cellular microtubules in interphase were visualized using indirect immunofluorescence techniques as previously described.\(^5^6\) Cells were treated for 18 h with vehicle or drug, fixed with methanol and microtubules visualized with a β-tubulin antibody using a Nikon Eclipse 80i fluorescence microscope. Percent microtubule depolymerization as compared to vehicle treated controls was determined visually.

**Molecular Modeling**
Sybyl 8.1\(^5^7\) was used to prepare the X-ray crystal structure models of αβ-tubulin complexed with different ligands (pdbid: 1sa0, 1sa1, 3hkc, 3hkd and 3hke).\(^5^8,5^9\) For each structure, the procedure was the same as previously reported.\(^5^0\) The stathmin-like domain, the C and D subunits, were deleted. Hydrogen atoms were added and their orientations were optimized by the Tripos force field to a gradient of 0.005 kcal mol\(^{-1}\) Å\(^{-1}\). GOLD 5.1\(^5^1\) was used for docking studies. The ligands were docked in the active site, which was defined by the space in a 6 Å radius around the complexed small molecule. One hundred GA runs generated one hundred docking conformations for each ligand with GOLD and were filtered initially by GoldScore. They were further analyzed with HINT.\(^5^2\) First, the ligands were docked to all five tubulin structures with GOLD without constraints. The resulting conformations were rescored with HINT and the best docking poses were indicated by the highest HINT score. Next, the differences between ligand binding to the five receptors for each ligand were checked and it was found that binding with 3hkc generally gave higher scores. The resulting 3hkc-ligand complexes were further minimized with the Tripos force field and rescored again. The minimized conformation and the new HINT score were defined as the docking conformation/binding mode and binding score of the ligand.

It is important to note that although it binds in a similar fashion, the complexed ligand in 3hkc, N-[2-[(4-hydroxyphenyl)amino]pyridin-3-yl]-4-methoxybenzenesulfonamide (Figure S5) is structurally different from the pyrrole-based compounds reported here or colchicine.
