Supplementary Information

A Luminescent Assay for Ketones and Aldehydes Employing Catalytic Signal Amplification

Ronald J.T. Houk and Eric V. Anslyn*

Excitation and Emission Profiles

9,10-Dibromoanthracene

Emission scan: excite 381 nm, $\lambda_{\text{max,em}}=406$ nm. Excitation scan: emit 430 nm, range 225-420 nm, $\lambda_{\text{max,ex}}=402$ nm

9-bromo-10-(phenylethynyl)anthracene

Emission scan: excite 405 nm, $\lambda_{\text{max,em}}=437$ nm. Excitation scan: emit 464 nm, range 242-454 nm, $\lambda_{\text{max,ex}}=430$ nm
9,10-bis(phenylethynyl)anthracene

Emission scan: excite 436 nm; $\lambda_{\text{max,em}} = 470$ nm. Excitation scan: emit 500 nm, range 260-490 nm, $\lambda_{\text{max,ex}} = 463$ nm

9,10-diphenylanthracene

Emission scan: excite 373 nm; $\lambda_{\text{max,em}} = 407$ nm. Excitation scan: emit 407 nm, range 250-402 nm, $\lambda_{\text{max,ex}} = 393$ nm
2,5-diphenyloxazole

Emission scan: excite 316 nm: $\lambda_{\text{max}}^\text{em}=359$ nm. Excitation scan: emit 359 nm, range 250-349 nm, $\lambda_{\text{max}}^\text{ex}=315$ nm.

Comparison of excitation spectra.

The excitation spectrum of PPO falls nicely within the trough of the anthracene dyes, allowing for unspoiled excitation of just PPO. No energy transfer activity was observed between PPO and the anthracene dyes.
Trace of Chemiluminescent Turn-on

This sample is from a Suzuki assay utilizing 93% cinnamaldehyde vs. ethaneditiol. Conversion of 9,10-dibromoanthracene to DPA was quite facile and the increase in chemiluminescence intensity increased from less than 20,000 counts/s to well over 160,000. Data was recorded at 431 nm.

Spectra from Luminescing Samples

For the same determinations as the previous chart, spectra were taken upon plateauing of the intensity output. The energy associated with the peroxoanalate initiation mechanism appears to favor the second peak of the vibrational fine structure.
