Experimental Section

**Caution:** 1,1'-azobis(5-methyltetrazole) reported in this publication is very sensitive towards friction, impact, and electrostatic discharge. Therefore proper safety precautions should be taken when handling these compounds. Laboratories and personnel should be properly grounded, and safety equipment such as Kevlar gloves, leather coats, face shields, and ear plugs are recommended.

**General methods:** All chemical reagents and solvents (analytical grade) were used as supplied unless otherwise stated. $^1$H and $^{13}$C spectra were measured with a Bruker Avance III 500 MHz Digital NMR Spectrometer operating at 500, 126 MHz. All chemical shifts are quoted in ppm relative to TMS ($^1$H, $^{13}$C). FT-IR spectra was recorded on a BOMEM MB Series 154S FTIR spectrometer. Raman spectra was measured with a RamTracer®-200 instrument. Mass spectra was recorded on Finnigan TSQ Quantum ultra instrument using electro spray ionization (ESI) method. Elemental analysis was performed by on a Vario EL III recorder. TG and DSC studies were carried out on a STD-Q600 at a heating rate of 5 °C·min$^{-1}$ in closed Al containers with a nitrogen flow of 80 mL·min$^{-1}$ (0.162 mg of powder). The electrostatic sensitivity test was carried out using an Electric Spark Tester ESD JGY-50 III.

X-ray Structural Analysis of 5

Single crystals of 5 suitable for X-ray crystallographic analysis were obtained by slow evaporation from the mixture of acetone and ethyl acetate solution at room temperature.

The X-ray diffraction measurements for 5 were carried out on a Rigaku RAXIS-RAPID imaging plate diffractometer at 291 K by using graphite-monochromated Mo Kα radiation (λ = 0.71075 Å). Data were collected by ω scan technique. The structure was solved by direct methods with SHELXS-97 and expanded by using the Fourier technique. The non-hydrogen atoms were refined anisotropically. The hydrogen atoms were located and refined. Please see its CIF files. Relevant data are given in Table S2.

Computation details

Computations were carried out by using the Gaussian03 suite of programs. The elementary geometric optimization and the frequency analysis were performed at the level of Becke three Lee-Yan-Parr (B3LYP) Functionals¹ with 6-311+G** basis set². All of the optimized structures were characterized to be local energy minima on the potential surface without any imaginary frequencies.
The gas phase heat of formation (HOF) of 5 (Table S4) was determined by using the method of permutation reactions\(^3\). For the azo compounds reported here, the permutation reactions were carried out as Hakima Abou-Rachid did\(^4\) (Scheme S1). The accuracy of the method was also proved by the HOF prediction of 5, as shown in Table S4. According to the optimized structure, the total energy (\(E_0\)) and thermodynamic parameters, including zero point energy (ZPE) and thermal correction to Enthalpy (HT), were obtained at the B3LYP/6-311+G** level\(^5\).

</table>

\(^{[a]}\) Scale factor for ZPE and vibrational frequencies is 0.96.

**Detonation Parameters**

Detonation velocity (\(D\)) and detonation pressure (\(P\)) were evaluated by the empirical Kamlet formula as

\[
P = 1.558 \, \rho^2 \Phi \quad (1)
\]

\[
D = 1.01 \, \Phi^{1/2} (1+1.30 \rho_0) \quad (2)
\]

\[
\Phi = 0.4889 \, N \, (M \, Q)^{1/2} \quad (3)
\]

where \(D\) is the predicted detonation velocity (km/s) and \(P\) is the detonation pressure (GPa), \(\rho\) is the density of a compound (cm\(^3\)/mol). \(\Phi, N, M\) and \(Q\) are characteristic parameters of an explosive, \(Q\) is chemical energy of detonation (kJ/g). The crystal
densities and the calculated heats of formation were used in computing the D and P values.
