Supplementary Information

Experimental

1. Catalyst preparations: Graphitic carbon nitride (g-C\textsubscript{3}N\textsubscript{4}) was synthesized by thermal treatment of three precursors respectively (urea, thiourea and dicyandiamide, 10 g, AR, Sinopharm Chemical Reagent Co., Ltd) in a crucible with a cover under ambient pressure in air. After dried at 80°C for 24 h, the precursor was put in a Muffle Furnace (Isotemp Programmable Muffle Furnace 650-750 Series, Fisher Scientific) and heated to 550°C for 3 hours to complete the reaction. The powders were washed with nitric acid (0.1 mol L\textsuperscript{-1}) and distilled water to remove any residual alkaline species (e.g. ammonia) adsorbed on the sample surface, and then dried at 80°C for 24 h. The as-prepared samples were denoted as UCN, TCN and DCN. The prepared
powders were yolk yellow/orange/bright yellow color respectively (Fig S6).

2. Characterization: The X-ray diffraction (XRD) measurements were performed with X’Pert-Pro MPD with Cu Kα (λ=1.5406 Å). The surface morphologies of the polymer were determined by transmission electron microscopy (TEM) observed on Tecnai G2 F20 S-Twin (FEI, 200 kV). Chemical compositions and element binding energies of g-C₃N₄ were analyzed using X-ray photoelectron spectroscopy (XPS) on Perkin-Elmer RBD upgraded PHI-5000C ESCA system with Al Kα x-ray as an excitation source. FTIR spectra were recorded on Nicolet 6700 IR spectrometer by using KBr pellets. UV-Vis diffuse-reflectance spectra (UV-Vis DRS) were recorded on Cary 5000 with Integrating Sphere Attachment (incident angle to reflecting sample: 12.5°). Photoluminescence measurements (PL) were conducted on HITACHI F-4600 fluorescence spectrophotometer. N₂ adsorption-desorption analyses were carried out at 77 K using Micromeritics Tristar II 3020 M.

3. Photocatalytic activity measurements: Reactions were carried out in a Pyrex top-irradiation reaction vessel connected to a glass closed gas circulation system. Photoreduction of H⁺ to H₂ was performed in pure water, as well as aqueous solutions containing some sacrificial agent. H₂ production half reaction was performed by dispersing 80 mg of g-C₃N₄ catalyst powder in pure water (100 ml) or an aqueous solution (100 mL) containing triethanolamine (TEA, 10 vol. %) as a sacrificial reagent. In the case of deposition of Pt, an appropriate amount of H₂PtCl₆ was dissolved in the reactant solution and pre-loaded on the g-C₃N₄ under ultraviolet irradiation. The reactant solution was evacuated for one hour to remove air
completely prior to irradiation under a PLS-SXE 300 Xe lamp and a water filter. The wavelength of the incident light was controlled by using an appropriate cut-off filter to provide simulated sunlight. The temperature of the reactant solution was maintained at room temperature by a flow of cooling water during the reaction. The evolved gases were analyzed by gas chromatography.

![FT-IR spectra](image)

Figue S1. The FT-IR spectra of the obtained graphitic carbon nitride powders (UCN, TCN and DCN). The spectra present several major bands between 1200 cm\(^{-1}\) and 1650 cm\(^{-1}\) region. The peaks at about 1241, 1319, 1411, 1457, 1569, 1639 cm\(^{-1}\), belong to the characteristic stretching modes of CN heterocycles. In addition, the breathing mode of triazine units at 809 cm\(^{-1}\) was presented. The results are well consistent with former reports.\(^1\)
Figure S2. The XPS spectra of the powders prepared at 550°C of UCN, TCN and DCN from bottom to top.
Figure S3. The XPS spectra of UCN: (a) C 1s, (b) N 1s, (c) O 1s.
XPS measurements can provide us more detailed information on the chemical composition and element status of C, N elements (Figure S3a-b). Figure S3a shows two C 1s peaks centering at 288.0 eV and 284.6 eV, corresponding to sp²-bonded carbon (N=C=N) and graphitic carbon respectively. In Figure S3b, the N 1s spectrum
can be fitted into four binding energies. Two main signals at 398.5 eV and 399.3 eV are exhibited. The former peak shows occurrence of C-N=C groups (denoted as N1). The second peak relate to either tertiary nitrogen N-(C)3 groups linking structural motif (C6N7) or amino functions carrying hydrogen ((C)2-N-H) in connection with structural defects and incomplete condensation (denoted as N2). A weak peak at 401.0 eV corresponds to N bonded three carbon atoms in the aromatic cycles. The 404.3 eV peak is attributed to the \( \pi \)-excitations.
Figure S4. The XPS spectra of TCN. (a) C 1s, (b) N 1s, (c) O 1s, (d) S 2p. The spectra of TCN are similar to UCN. Careful examination of S 2p spectrum of the TCN sample (Figure S4d), the existence of sulfur is clearly evidenced.

Figure S5. The XPS spectra of DCN. (a) C 1s, (b) N 1s, (c) O 1s. The spectra of DCN are similar to UCN.
Figure S6. The pictures were yolk-yellow UCN, orange TCN and bright yellow DCN from left to right.
