Materials and methods

Materials and instruments: Thiamethoxam (99.7%) was purchased from Sigma-Aldrich and used without further purification. The UV-Vis absorption spectra were recorded on a spectrophotometer (Cintra 20, GBC, and Australia). The corrected fluorescence spectroscopic studies were performed on a fluorescence spectrophotometer (Horiba Jobin Yvon FluoroMax-4 NIR, NJ, USA) at room temperature (25 °C). The particle sizes of drug-dendrimers complexes were measured in triplicate using a Zetasizer Nano ZS (Malvern Instruments, Southborough, MA).

Isothermal Titration Calorimetry

Calorimetric titrations were carried out on a Nano ITC Standard Volume (TA Instruments, New Castle, DE, USA) with an active cell volume of 1.0 mL. All experiments were run at 25 °C in water. The dendrimer solutions (65 μM, 250 μL) were injected into a water solution of rug (138 μM, 1 mL). Each titration consisted of twenty-five, 10 μL injections at 300-second intervals with stirring speed of 250 rpm. The gap between two consecutive injections was 300
seconds, in order to allow the system to reach the equilibrium after each injection. The dilution of dendrimer solutions upon addition to the pure buffer solution placed in the cell was also determined, using the same number of injections and the same concentration employed in the titration experiment. The heats of interaction during each injection were measured by integration of each titration peak using the ORIGIN 7 software (OriginLab Co. Northampton, MA, delivered with the ITC). For each injection, the dilution heats determined in the control experiment were subtracted from the heats obtained in the interaction experiment. The resulting corrected heats of the interaction curve were used for the calculations of the molar enthalpy, equilibrium constant, entropy, and Gibbs free energy of the reaction.

**Cell culture medium:** Drosophila S2 cells were propagated in Schneider’s Drosophila Medium (Sigma) supplemented with 10% FBS, 100 U/mL penicillin and 100 μg/mL streptomycin at 25 °C without CO₂.

**Cytotoxicity assay:** Cytotoxicity was monitored using Tali™ viability kit-Dead Cell Green (Invitrogen, Catalog A10787) that was a green-fluorescent nuclear and chromosome stain. It does not penetrate intact membranes, but easily penetrate compromised membranes characteristic of dead cells. The measurement was performed at 48 h post-incubation of dendrimer/drug complexes or drug only. Next, replace the fresh cell medium after 48 h of incubation and then add 1 μL Dead Cell Green into 100 μL cell medium for 0.5 h incubation.

**Insects raising:** Insect larvae of Heliothis armigera were fed with artificial diet containing the drug carrier G2 from first to third instar, then the guts of the third instar larvae were dissected and observed under a fluorescence microscope. The second instar larvae were picked out and individually fed with artificial diet mixed with G2/thiamethoxam complexes or thiamethoxam alone. Each larva was fed with 7.2 μg drug and 24 μg G2 in total. The developmental status of the treated larvae was observed.
