**General methods**

**NMR titration experiments.** Association constants ($K_a$) were determined in D$_2$O at 313 K by measuring the proton chemical shift variations in the $^1$H NMR spectra of a solution of the βCD derivative in the presence of increasing amounts of the corresponding chaperone. In a typical titration experiment, a solution of the host (ManS)$_3$-βCD (1.63 mM) in D$_2$O was prepared, a 500 μL aliquot was transferred to a 5-mm NMR tube, and the initial NMR spectrum was recorded. A concentrated solution (ca. 25 mM) of the chaperone 6S-NOI-NJ and 6S-NAdB-NJ in the previous solution was prepared in order to maintain the host concentration constant all throughout the titration experiment. 10 μL aliquots of this solution were sequentially added to the βCD solution and the corresponding NMR spectra recorded until 90-100% complexation of the guest had been achieved. The chemical shifts of the diagnostic signals obtained at 10-15 different host-guest concentration ratios were used in an iterative least-squares fitting procedure (Figures S4-S5).

**Isothermal titration calorimetry (ITC).** In addition to information in the Experimental Section of the manuscript, the lectin solns to be used for ITC were prepared in 0.1 M sodium phosphate buffer (pH 7.4) containing 0.1 mM Ca$^{2+}$ and 0.1 mM Mn$^{2+}$, dialysed against a large volume of the same buffer and centrifuged to remove any insoluble material. The protein concentrations were determined colorimetrically following the Bradford method, measuring the absorbance at 595 nm of a solution (1 mL) containing 200 μL of the commercial reagent (BIO-RAD protein assay), distilled water (780 μL) and 20 μL of protein solution containing 2-10 μg of protein. Calibration of the commercial reagent was carried out using a 10% (w/v) solution of BSA. The extinction coefficient determined for the colorimetric complex was $\varepsilon_{595} = 45$ mL·mg$^{-1}$·cm$^{-1}$. 
Preparation of \( N \)-dansyl-2,2,2-tris\[5-(\alpha-D\)-mannopyranosylthio]-2-oxapentyl]ethyl amine (8). A solution of 2,2,2-tris\[5-(2,3,4,6-tetra-\(O\)-acetyl-\(\alpha\)-D-mannopyranosylthio)-2-oxapentyl]ethyl azide 9 (106 mg, 77 \(\mu\)mol) in MeOH (5 mL) was treated with a NaOMe (10% eq, 1 M methanolic solution, 92 \(\mu\)L) for 3 h. The solution was stirred at room temperature for 30 min, and then neutralised using Amberlite IR-120 (\(H^+\)) ion exchange resin, filtered and concentrated to dryness. The resulting deacetylated azide was then hydrogenated by treatment with 10% Pd/C (20 mg) under a \(H_2\) atmosphere (1 atm) for 16 h. The reaction mixture was filtered and the solvents evaporated. The crude amine 10 thus obtained was dissolved in anhydrous DMF (2.3 mL) and the solution was cooled to 0 °C. Triethylamine (17 \(\mu\)L, 0.12 mmol) and 5-dimethylaminonaphtalene-1-sulfonyl chloride (32 mg, 0.12 mmol) were added and the reaction mixture was stirred for 24 hours at room temperature. The solvent was subsequently removed under reduce pressure and the residue was purified by column chromatography using 50:10:1 \(\rightarrow\) 50:10:1 DCM-MeOH-H\(2\)O as eluent.
