**General method:** Unless stated otherwise, reactions were performed under nitrogen atmosphere using oven dried glassware. Reactions were monitored by thin layer chromatography (TLC) on silica gel plates (60 F254), visualizing with ultraviolet light or iodine spray. $^1$H and $^{13}$C NMR spectra were recorded in CDCl$_3$/DMSO-d$_6$ solution by using a 400 MHz spectrometer (VARIAN 400 MR). Proton chemical shifts ($\delta$) are relative to tetramethylsilane (TMS, $\delta = 0.00$) as internal standard and expressed in ppm. Spin multiplicities are given as s (singlet), d (doublet), t (triplet), dd (doublet of doublet), td (triplet of doublet) and m (multiplet) as well as bs (broad). Coupling constants (J) are given in hertz. Infrared spectra were recorded on a FT-IR spectrometer (FT/IR-4200, JASCO). Melting points were determined by using melting point apparatus (Buchi melting point B-540) and are uncorrected. MS spectra were obtained on a mass spectrometer (AGILENT 6430 triple quadrupole LC-MS). Chromatographic purity by HPLC (Agilent 1200 series Chem Station software) was determined by using area normalization method and the condition specified in each case: column, mobile phase (range used), flow rate, detection wavelength, and retention time.

**General procedure for the preparation of compound 3:**

A mixture of TFAA (2.093 mmol) and benzoic acid (0.598 mmol) was stirred for 20 min until the solid was dissolved. After stirring for additional 20 min, carbazole, 1 (0.598 mmol) was added in one portion. To this mixture was added 85% H$_3$PO$_4$ (0.059 mmol) drop wise for a duration of 20 min. The mixture was then stirred for 2h (monitored by TLC) and the excess of TFA/TFAA was distilled out at atmospheric pressure. The remaining liquid was partitioned between ethyl acetate (30 mL) and H$_2$O (15 mL). The organic layer was separated and washed with 5% NaOH (7 mL) and then brine (8 mL). The mixture was dried over anhydrous Na$_2$SO$_4$, filtered and concentrated under vacuum. The residue was purified by column chromatography using EtOAc-n-hexane to give the desired product 3.

Cell Proliferation Assay

The anti-proliferative activity and cancer cell selectivity of the synthesized compounds on normal and cancer cells was evaluated using the SRB (Sulforhodamine B) cell proliferation assay. This assay was chosen because of its sensitivity, large dynamic range and the ability to measure cell proliferation over three days with normalization to initial cell number as well as to vehicle-treated cells. Further, this assay is the standardized assay of choice for anticancer compound screening at the National Cancer Institute (NIH). The SRB assay provides a colorimetric readout which can be spectrophotometrically measured and does not involve antibodies or toxic reagents. The assay is based on detection of total protein content of cells, which increases or decreases in proportion with cell number.

In brief, the assay was performed as follows: Cancer(Cal 27(oral cancer cell line) and MDA-MB231(breast cancer cell line)) and non-cancer (Human Embryonic Kidney (HEK) 293T cell line) cells were seeded in 96-well plates and incubated overnight. The optimum cell numbers to be seeded were determined by a growth curve analysis for each cell line. In the initial (single dose) screen, compounds (dissolved in 100% DMSO to a stock concentration of 100mM) were added to the adhered cells at a final concentration of 10μM. After 72h of treatment, the cells were washed with phosphate-buffered saline and ice-cold 10% trichloroacetic acid added to the cells to precipitate all proteins for 1h at 4°C. The cells were then washed with water and air-dried. Cellular proteins were then stained using 0.4% SRB solution in 1% acetic acid for 10 min at room temperature. The unbound dye was washed away by destaining with 1% acetic acid and
bound dye solubilized with 10mM Tris solution. Absorbance of solubilized dye was measured at a wavelength of 590 nm. Percentage growth was determined by the formula \([\frac{At-A0}{Ac-A0}] \times 100\), where \(At=\) absorbance after 72h of test compound treatment, \(A0=\) Absorbance at time 0, \(Ac=\) Absorbance after 72h without treatment. (Compounds which resulted in <50% growth of cancer cells were considered potentially anti-proliferative. Among such compounds, those which retained >75% growth of non-cancerous cells were considered potentially selective to cancer cells). The Graphpad Prism 5 Demo software was used to generate the dose response curve using the sequence: select table and graph – enter data – analyze – transform data – nonlinear regression – inhibition vs response – results.
