Organocatalysts of Oxidative Protein Folding
Inspired by Protein Disulfide Isomerase

I. General

Commercial reagents were used without further purification. β-Mercaptoethanol (βME), oxidized β-mercaptoethanol (βME\textsuperscript{ox}), and diethylenetriamine were from Sigma–Aldrich (St. Louis, MO). RNase A was from Sigma–Aldrich and purified further by cation-exchange chromatography. The RNase A substrate 6-FAM–dArUdAdA–6-TAMRA was from Integrated DNA Technologies (Coralville, IA). All glassware was oven- or flame-dried, and reactions were performed under N\textsubscript{2}(g) unless stated otherwise. Dichloromethane (DCM) and tetrahydrofuran (THF) were dried over a column of alumina. Triethylamine was dried over a column of alumina and purified further by passage through an isocyanate scrubbing column. Flash chromatography was performed with columns of 40–63 Å silica, 230–400 mesh from Silicycle (Québec City, Canada). Thin-layer chromatography (TLC) was performed on plates of EMD 250-μm silica 60-F\textsubscript{254}. The term “concentrated under reduced pressure” refers to the removal of solvents and other volatile materials using a rotary evaporator at water aspirator pressure (<20 torr) while maintaining the water-bath temperature below 40 °C. Residual solvent was removed from samples at high vacuum (<0.1 torr). The term “high vacuum” refers to vacuum achieved by a mechanical belt-drive oil pump. Analytical samples of all protein folding catalysts were obtained with a preparative HPLC instrument from Shimadzu (Kyoto, Japan), which was equipped with a C18 reverse-phase preparative column, a Prominence diode array detector, and fraction collector. Equilibrium and reduction potential assays were performed using an analytical HPLC instrument from Waters (Milford, MA), which was equipped with a Waters 996 photodiode array detector, Empower 2 software, and a Varian C18 reverse-phase column. Thiol pK\textsubscript{a} values were determined with a Varian Cary 60 UV–Vis spectrophotometer. Fluorescence was measured with an Infinite M1000 plate reader from Tecan (Männedorf, Switzerland). Calculations and rate constants were performed with Prism 6 software from GraphPad (La Jolla, CA). All NMR spectra were acquired at ambient temperature with a Bruker DMX-400 Avance spectrometer and Bruker III 500ii with...
cryoprobe spectrometer at the National Magnetic Resonance Facility at Madison (NMRFAM), and were referenced to TMS or residual solvent.

II. Chemical synthesis

BMC (1) was synthesized as a racemate from (±)-trans-1,2-diaminocyclohexane as described previously.\(^1\) An analytically pure sample of BMC was obtained by reverse-phase HPLC using a preparatory C18 column and a linear gradient of 10–80% v/v acetonitrile (0.1% v/v TFA) in water (0.1% v/v TFA) over 45 min. BMC eluted at 23 min and, after lyophilization, was isolated as a white solid.

To a flame-dried round-bottom flask was added \(9 \) (0.847 g, 4.166 mmol), which was synthesized as described previously.\(^2\) Fifty mL of dichloromethane was then added, and the resulting solution was cooled to 0 °C under an atmosphere of \(N_2(g)\). Next, triethylamine (2.3 mL, 16.667 mmol) and chloroacetic anhydride (1.567 g, 9.167 mmol) were added, and the reaction mixture was stirred for 30 min before being quenched by the addition of 50 mL of saturated \(\text{NaHCO}_3(aq)\). The organic layer was extracted and washed with water (2 × 25 mL). The organic extract was then dried over \(\text{MgSO}_4(s)\), filtered, and concentrated under reduced pressure, and the product was purified by column chromatography (silica, EtOAc) yielding \(10\) as a colorless oil (1.154 g, 78%).

Compound 10 (1.154 g, 3.239 mmol) was placed in a round-bottom flask and dissolved in 30 mL of dichloromethane, and the resulting solutions was placed under an atmosphere of N$_2$(g). Triethylamine (2.3 mL, 16.208 mmol) and thioacetic acid (0.5 mL, 7.131 mmol) were then added, and the resulting solution was stirred under N$_2$(g). After 16 h, the reaction mixture was concentrated, and the product was purified by column chromatography (silica, EtOAc), giving 11 as a colorless oil (2.792 g, 86%).

A flame-dried round-bottom flask was charged with 11 (0.178 g, 0.409 mmol) and placed under an atmosphere of N$_2$(g). Four mL of anhydrous methanol followed by 2 mL of 3 N HCl in methanol were then added, and the reaction mixture was stirred under N$_2$(g). Upon confirmation by TLC that the Boc group had been removed, the reaction mixture was concentrated under reduced pressure, and the product was purified by reverse-phase HPLC using a preparatory C18 column and a linear gradient of 10–50% v/v acetonitrile (0.1% v/v TFA) in water (0.1% v/v TFA) over 55 min. Dithiol 2 eluted as its TFA salt at 12.5 min and, after lyophilization, was isolated as a white solid (0.108 g, 72%).

Synthesis of compound 12 was accomplished by closely following a procedure reported previously. Specifically, diethylenetriamine (2.003 g, 19.415 mmol) and triethylamine (8.1 mL, 58.245 mmol) were dissolved in 100 mL of THF, and the resulting solutions was cooled to 0 °C in an ice bath and placed under an atmosphere of N\textsubscript{2}(g). Next, a solution of 2-(boc-oxyimino)-2-phenylacetonitrile (Boc-ON) (9.563 g, 38.832 mmol) in 40 mL of THF was added dropwise. The reaction mixture was stirred for 1 h on ice and then for another 1 h at room temperature. The solvent was removed under reduced pressure, and the residue was dissolved in 200 mL of dichloromethane and washed with 5% w/v NaOH. The organic extract was then dried with MgSO\textsubscript{4}(s), filtered, concentrated under reduced pressure, and the product was purified by column chromatography (silica, 10% v/v methanol in dichloromethane, 1% ammonium hydroxide), yielding 12 as a colorless oil (5.184 g, 88%).

Compound 12 (0.419 g, 1.381 mmol) was placed in a flame-dried round-bottom flask, dissolved in 15 mL of anhydrous dichloromethane, and cooled to 0 °C in an ice bath under an inert atmosphere. Triethylamine (0.72 mL, 5.17 mmol) and acetyl chloride (0.16 mL, 2.29 mmol) were then added, and the resulting solution was stirred at 0 °C for 1 h and at room temperature for another 2 h. The reaction mixture was then concentrated under reduced pressure, and the product was purified by column chromatography (silica, EtOAc), yielding 13 as a colorless oil (0.425 g, 89%).

Forty mL of 4 M HCl in dioxane was added to a round-bottom flask containing 13 (0.425 g, 1.230 mmol). The resulting solution was stirred overnight and then concentrated under reduced pressure. The product was then partially dissolved in 20 mL of dichloromethane, and the resulting slurry was cooled to 0 °C in an ice bath and placed under an atmosphere of N\textsubscript{2}(g).
Triethylamine (1.1 mL, 7.9 mmol) and chloroacetic anhydride (0.463 g, 2.706 mmol) were then added, and the reaction mixture was stirred for 30 min before being quenched by the addition of 50 mL of saturated NaHCO3(aq). The organic layer was extracted and washed with water (2 × 25 mL). The organic extract was then dried with MgSO4(s), filtered, and concentrated under reduced pressure, and the product was purified by column chromatography (silica, 10% v/v methanol in dichloromethane), yielding 14 as a colorless oil (0.245 g, 67%).

**III. Determination of thiol pK\(_a\) values**

The thiol pK\(_a\) values for 2 and 7 were determined by following closely a procedure reported previously that exploits the elevated absorbance of the deprotonated thiolate at 238 nm.\(^4\) A plot of \(A_{238}\) vs pH was recorded (Fig. S1), and pK\(_a\) values were determined by fitting these data to eq 1, which was derived from Beer’s law and the definition of the acid dissociation constant.\(^1,5\)

\[
A_{238} = C_T \left( \frac{\varepsilon_{\text{SH}}^S - 10^{\text{pH}-\text{pK}_a^2} + \varepsilon_{\text{SH}}^S - 10^{\text{pK}_a - \text{pH}}}{10^{\text{pH}-\text{pK}_a} + 1 + 10^{\text{pK}_a - \text{pH}}} \right)
\]  

(1)

In eq 1, \(C_T\) is the total thiol concentration, \(\varepsilon_{\text{SH}}^S\) is the extinction coefficient of the doubly protonated form of 2, 5, or 7, \(\varepsilon_{\text{SH}}^S\) is the extinction coefficient of the singly protonated form of 2, 5, or 7, and \(\varepsilon_{\text{S}^-}^S\) is the extinction coefficient of the doubly deprotonated form of 2, 5, or 7.

IV. Determination of disulfide $E^{'o}$ values

The reduction potentials of BMC, 2, 5, and 7 were determined as described previously.$^{1,5,6}$ Briefly, an equilibrium was established between reduced BMC (or 2, 5, or 7) and $\beta$MEox, and analyzed with analytical HPLC. The equilibrium concentrations were determined by integration of the peaks corresponding to $\beta$ME and $\beta$MEox. From these concentrations, the $K_{eq}$ for the reaction was determined and the reduction potential of BMC (or 2, 5, or 7) was then calculated using the Nernst equation and $E^{\beta MEox}_{o} = -0.260$ V. The values reported are the mean (±SE) of three separate measurements for each compound.

V. Assay for disulfide-bond isomerization activity

sRNase was prepared as described previously.$^{7}$ Bovine liver PDI was from Sigma–Aldrich (product #P3818). The activation of sRNase A in the presence of refolding catalysts was determined as described previously.$^{1}$ Refolding reactions were performed at 30 °C in 50 mM Tris–HCl buffer, pH 7.6, containing GSH (1.0 mM), GSSG (0.2 mM), and catalyst (1.0 mM). Organocatalysts were delivered from 100-fold concentrated stock solutions in DMSO. Reactions were initiated by the addition of sRNase A to a final concentration of 5 µg/mL. Reaction progress was monitored by quantifying the cleavage of the RNase A substrate 6-FAM–dArUdAdA–6-TAMRA at 493/515 nm, as described previously.$^{8}$ Assays were performed in triplicate at ambient temperature in a black polystyrene 96-well plate, in 200 µL of 0.10 M MES-NaOH buffer, pH 6.0, containing NaCl (0.10 M). The resulting fluorescence data were fitted to the equation $k_{cat}/K_{M} = (\Delta I/\Delta t)/(I_f - I_0)[E]$, in which $\Delta I/\Delta t$ is the initial reaction velocity, $I_0$ is the fluorescence intensity before addition of any ribonuclease, $I_f$ is the fluorescence intensity after complete substrate hydrolysis, and [E] is the total ribonuclease concentration. Reaction progress was monitored every hour until the increase in activity leveled off (~5 h). In Fig. 4A, data were fitted to eq 2.$^{1}$
