Characterization
Nuclear magnetic resonance (NMR) spectra were recorded in DMSO-d₆ or CDCl₃ on a Bruker Avance II NMR spectrometer.¹ H NMR spectra were recorded at 400 MHz. Chemical shifts are referenced to internal solvent resonances and are reported relative to tetramethylsilane.

Elemental analyses (EA) were carried out with an Elementar Vario EL or Micro cube instrument.

Molecular weight distributions were measured by size exclusion chromatography (SEC) on a Polymer Laboratories/Varian PL-GPC 50 Plus system comprising a Polymer Laboratories 5.0 μm bead-size guard column (50 × 7.5 mm²), followed by three PL columns and a differential refractive index detector. The eluent was tetrahydrofurane (THF) at 35 °C with a flow rate of 1 mL·min⁻¹. The SEC system was calibrated using linear polystyrene standards ranging from 2000 g·mol⁻¹ to 2·10⁶ g·mol⁻¹ and the Mark-Houwink relationship for polystyrene (K = 14.1·10⁻⁵ dL·g⁻¹, α = 0.7).⁴

Static light scattering (SLS) measurements were performed using a MALLS-detector (multi-angle laser light scattering detector) SLD 7000 from Polymer Standard Services (PSS), Mainz, Germany. Five concentrations of the polymer were employed ranging from 0.5 g·L⁻¹
to 4.0 g L\(^{-1}\) to determine the weight-averaged molar mass \(M_w^{\text{SLS}}\) and the second virial coefficient \(A_2\). The solutions were prepared by dissolving the polymer in dimethyl acetamide (DMAc). After a stabilizing period of approx. 60 h, the solutions were filtered over 0.2 µL filters and analysed by SLS. The required \(dn/dc\) values were measured employing the same solutions with a refractometer \(dn/dc\) 2010 from PSS, Mainz, Germany.

General Procedure for Screening Reactions

Except the reactions with copper(II) sulfate as the catalyst, all reactions were conducted under an inert atmosphere. All solutions were degassed by percolating with argon. A solution of 0.2 mol·L\(^{-1}\) dialkyne and 0.4 mol·L\(^{-1}\) monoazide, 0.2 eq of the copper salt and the ligand or base, respectively, in DMF or THF was stirred at ambient temperature for 24 h. Subsequently, aqueous ammonium hydroxide was added to stop the reaction and the reaction mixture was
passed over a small column equipped with neutral alumina to remove the copper catalyst. The solvent was removed under reduced pressure and conversion was determined via $^1$H NMR spectroscopy in DMSO-$_d_6$ or CDCl$_3$. NMR data for complete clicked products:

Static Light Scattering (SLS) Measurements

SLS provides information on the time-averaged properties of the system. The apparent weight-averaged molar mass ($M_m$) can be obtained by the Debye relationship:

$$\frac{K \cdot c}{I_r} = \frac{1}{M_m} \left( 1 + \frac{R_g^2 \cdot q^2}{3} \right) + 2 \cdot A_2 \cdot c$$

Eq. S1

where $c$ is the concentration (in g·L$^{-1}$), $I_r$ is the relative excess scattering intensity, $K$ gathered optical parameters, $R_g$ is the radius of gyration, $q$ is the scattering wave vector, and $A_2$ is the second virial coefficient. The absolute weight-averaged molar mass, $M_m$, was obtained by extrapolating $\frac{K \cdot c}{I_r}$ values to $q = 0$ and $c = 0$ according to Eq. S1 (see Figures S6 for the Zimm-Plot of polymers P2e in dimethyl acetamide). SLS obtained molar weights are collected in Table 2.
