1. General Information

*Candida antarctica* lipase type B (CAL-B, Novozyme 435, 7300 PLU/g) was a gift from Novozymes. *Pseudomonas cepacia* lipase PCL-C I (1638 U/g) was purchased from Sigma-Aldrich and *Burkholderia cepacia* lipases PCL SD (24700 U/g) and PCL IM (943 U/g) were purchased from Amano Enzyme Inc. Alcohol dehydrogenase from *Ralstonia* sp. was generously given by Prof. Wolfgang Kroutil (University of Graz, Austria). All commercially obtained reagents were used as received unless otherwise noted. Solvents were distilled over an appropriate desiccant under nitrogen. Thin-layer chromatography (TLC) was conducted with Merck Silica Gel 60 F$_{254}$ precoated plates and visualized with UV and potassium permanganate stain. Column chromatography was performed using Merck Silica Gel 60 (230-400 mesh). NMR spectra were recorded on a Bruker DPX-300 or NAV-300 spectrometer at 300 ($^1$H), 282 ($^{19}$F) and 75 ($^{13}$C) MHz. Chemical shifts are reported in parts per million (ppm) relative to Me$_4$Si (δ 0.00) using deuterated solvent (CD$_3$OD or CDCl$_3$) as an internal standard. Data is reported as: s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet, ap = apparent; coupling constant(s) (J) in Hz; integration. IR spectra were recorded as thin films on NaCl plates or as KBr pellets on a Perkin-Elmer Spectrum 100 FT-IR and are reported in frequency of absorption (cm$^{-1}$). Mass spectra were obtained by positive or negative electrospray ionization (ESI) or atmospheric pressure chemical ionization (APCI) on a Hewlett-Packard 1100 chromatograph mass detector. High-resolution mass spectra (HRMS) were obtained on a Bruker MicroTofQ by ESI$^+$. Microwave reactions were carried out with a CEM Discover system S-Class microwave; conditions for all microwave reactions are as follows: temperature at 150 ºC, power at 200 W and pressure at 250 psi with medium to high stirring. Melting points were obtained on a Gallenkamp apparatus and are reported uncorrected. High pressure liquid chromatography (HPLC) was performed using a Hewlett-Packard 1100 with chiral columns Daicel Chiralcel OB-H, OJ-H and Chiralpak AS (25 cm x 4.6 mm) using mixtures of 2-propanol / hexanes as eluent and UV detection at 210, 215 and 254 nm. Optical rotations were obtained with a Perkin-Elmer 241 polarimeter, values are reported in 10$^{-1}$ cm$^2$ x degree x g$^{-1}$ (concentration, solvent).

3. Organocatalysis

The Michael addition of diethylmalonate 6 (1.2 equiv) to trans-chalcone 7 (1 equiv) was performed in a toluene-CH₂Cl₂ (300 μL + 60 μL) mixture in an eppendorf tube, with dry K₂CO₃ (3 equiv) and the corresponding imidazole derivative (0.5 equiv) at 25 °C at 900 rpm for 24 h. Afterwards, the reaction was stopped by filtering the crude in a short cotton plug pipette and evaporating the solvent. The crude was analysed by ¹H NMR for conversion and by HPLC (AS column) for the determination of the enantiomeric excess of the product 8 as previously done in our research group.²

The absolute configuration of the product 8 was demonstrated by comparison of its optical rotation value with the already described in the literature: [α]D²⁰ = -0.5 (c 1.0, CHCl₃) taken from the reactions with (1S,3R)-(−)-cis-IM-OH-Bu-Cl, (1S,3R)-(−)-cis-IM-OH-Oct-Br, (1S,3R)-(−)-cis-IM-OH-Oct-Cl, 6% ee and conversions values over 95%.³
4. Toxicity tests

The agar diffusion tests were performed as previously described in the literature.4

Individual Tables S1-S4 have been prepared to explain the influence of different parameters in the toxicity of the imidazolium derivatives:

Clearly NTf₂ species are the more toxic derivatives.

Little difference was observed for other anions although bromide and proline derivatives led to lower toxicity values.
