**Experimental Details**

*Preparation of RTILs:* $N_2N,N_2N$-trimethyl-$N$-propylammonium bis(trifluoromethanesulfonamide)

$([Me_3PrN][Tf_2N])$, $N_2N,N_2N$-triethyl-$N$-octylammonium bis(trifluoromethanesulfonamide)

$([Et_3OctN][Tf_2N])$, $N$-methyl-$N$-propylpyridinium bis(trifluoromethanesulfonamide)

$([MePrPyr][Tf_2N])$, $N$-butyl-$N$-methylpyridinium bis(trifluoromethanesulfonamide)

$([MeBuPyr][Tf_2N])$, 1-ethyl-3methylimidazolium bis(trifluoromethanesulfonamide)

$([EtMeIm][Tf_2N])$, 1-allyl-3-ethylimidazolium bis(trifluoromethanesulfonamide)

([AllyEtIm][Tf₂N]) were purchased from Kanto Chemical Co., Inc. $N$-methyl-$N$-methoxymethylpyridinium bis(trifluoromethanesulfonamide) ([Me(MeOMe)Pyr][Tf₂N]) was provided by Otsuka Chemical Co., Ltd. These RTILs were purified with the method described in previous reports before use.1-3

$N,N,N$-tributyl-$N$-methylammonium bis(trifluoromethanesulfonamide) $([Bu_3MeN][Tf_2N])$ and 1-hexyl-2,3-dimethylimidazolium bis(trifluoromethanesulfonamide) ([HexMeMeIm][Tf₂N]) were prepared by mixing exactly equal molar amounts of the purified organic chloride salts, $N,N,N$-tributyl-$N$-methylammonium chloride and 1-hexyl-2,3-dimethylimidazolium chloride, and Li[Tf₂N] in ultrapure water with dichloromethane. The solution was agitated at room temperature for 12 hrs. The dichloromethane phase containing RTIL was washed repeatedly with reverse osmosis (RO) water until the water phase was found to contain no chloride as determined by the addition of a few drops of a silver nitrate solution.3 Chemical structures of all RTILs used in this study are depicted in Figure S1.

*Preparation of Pt nanoparticle:* The RTILs were dried in vacuum prior to use. A soda glass plate ($2.5 \times 2.5$ cm), on which RTIL ($0.4$ mL) was spread, was set in a Cressington108 auto SE sputter coater. A Pt foil target ($ø5.7$ cm, 99.98 %) was placed on 4.5 cm above the glass plate. Sputter deposition onto RTIL for Pt nanoparticle preparation was conducted with sputter current of 40 mA in...
dry Ar (99.999 %) atmosphere whose pressure did not exceed 7 ± 1 Pa. The sputtering was conducted by direct current (DC) mode at room temperature (298 ± 2 K).

**Characterization of Pt nanoparticle and Pt–SWCNT composite:** Morphology of the obtained Pt nanoparticle and Pt nanoparticle-immobilized SWCNT (Pt–SWCNT) composite material was observed by a HITACHI H-7650 transmission electron microscope (TEM) with an acceleration voltage of 100 kV. Before the TEM observation, the sample grids were prepared by dropping the Pt sputtered-RTIL and the Pt–SWCNT dispersed isopropanol solution onto a TEM grid (ø3.0 mm, copper, 400 mesh) and a TEM microgrid (ø3.0 mm, copper, 167 mesh), respectively. The original TEM grids were coated with an amorphous carbon thin layer. Elemental analysis of the specimens was performed with an EDAX Genesis-XM2 energy dispersive X-ray spectrometer (EDX) mounted on the TEM. The Pt content in the Pt–SWCNT was measured by a Shimadzu ICPS-7510 inductively coupled plasma atomic emission spectrometer (ICP-AES). The chemical state of the elements contained in the Pt–SWCNT was examined by a KRATOS AXIS-ULYRA HSA X-ray photoelectron spectroscopy.

**Electrochemical experiments:** Electrocatalytic activities for a Pt nanoparticle–SWCNT (Pt–SWCNT) composite material prepared in this investigation toward oxygen reduction were examined with a Hokuto Denko HZ-5000 potentiostat/galvanostat controlled with a desktop computer. The electrochemical experiments were conducted by using a three-electrode cell. A glassy carbon (GC) rotating ring-disk electrode (RRDE) (Pt ring: 0.1866 cm²; GC disk: 0.2475 cm² (Pine Instruments)) was used as the working electrode. After preparation of Pt-SWCNT (1 mg) dispersed in i-propanol solution (0.2 mL), the solution of 5 μL was applied to the GC disk of the RRDE, and the i-propanol solution was evaporated in air. Finally the GC disk was covered with a Nafion® i-propanolic solution of 5 μL to robustly fix the Pt–SWCNT on the GC. A Pt mesh was used as the counter
electrode. The Ag/AgCl double-junction electrode immersed in a KCl-saturated solution was employed as the reference electrode. All potential values are reported with respect to normal hydrogen electrode (NHE). The prepared Pt–SWCNT working electrode was pretreated with multiple potential scans between 0 and +1.2 V (vs. NHE) in 0.1 M HClO₄ aqueous solution under dry N₂ condition before oxygen reduction experiments. Cyclic voltammograms were recorded at the Pt–SWCNT modified RRDE electrode in 0.1 M HClO₄ aqueous solution saturated with N₂ or O₂ gas. Prior to the measurements, the solution was aerated with N₂ or O₂ more than 30 min. Hydrodynamic voltammetry was carried out under O₂ atmosphere. The scan rate was 10 mV s⁻¹ and the rotating rate was 1200 rpm. The potential at the ring was maintained at 1.20 V (vs. NHE) so as to entirely oxidize hydrogen peroxide (H₂O₂) generated by an undesirable two-electron O₂ reduction reaction. H₂O₂ generation rate, \( x_{\text{H}_2\text{O}_2} \), on the GC disk was calculated from the following formula

\[
x_{\text{H}_2\text{O}_2} = \frac{200I_R/N}{I_D + I_R/N}
\]

where \( I_R \) is the ring current, \( I_D \) is the disk current and \( N \) is the collection efficiency, here, the \( N \) value was 0.40. By this electrochemical analysis, we can estimate the percentage for the two-electron reaction involved in the electrochemical O₂ reduction reaction at each potential as \( x_{\text{H}_2\text{O}_2} \).

**Additional Results and Discussion**

*Electrochemical oxygen reduction experiments:* Metal nanoparticle–CNT composite material is expected to be a next-generation electrode catalyst for polymer electrolyte fuel cell (PEFC). There are many papers on electrocatalytic characteristics of metal nanoparticle–SWCNT composite. We examined electrocatalytic activity of the Pt–SWCNT prepared by the method depicted in Scheme S1 to oxygen reduction reaction (ORR). The Pt–SWCNT modified GC disk (Pt–SWCNT/GC) electrode was prepared by the method described in Experimental Details. The prepared Pt–SWCNT working electrode was pretreated with multiple potential scans between 0 and +1.2 V (vs. NHE) in 0.1 M
HClO₄ aqueous solution under dry N₂ condition before the electrochemical experiments. Fig. S6 shows cyclic voltammograms recorded at the Pt–SWCNT/GC electrode in 0.1 M HClO₄ aqueous solution saturated with N₂ or O₂ gas. Under N₂ atmosphere, several characteristic waves appeared at 0.60 to 1.20 V (vs. NHE) and 0.05 to 0.30 V. The former is attributable to oxidation/reduction of Pt atoms on the surface of Pt nanoparticle, and the latter is due to adsorption/desorption of hydrogen atoms onto the Pt nanoparticle. When the voltammetry was conducted in the O₂ atmosphere, a distinctive O₂ reduction wave appeared at negative potential than ca. 0.90 V. Further investigation was carried out by means of hydrodynamic voltammetry using a rotating ring-disk electrode in order to elucidate whether the O₂ reduction proceeds by a useful four-electron reduction process. From the voltammograms shown in Fig. S7, we can determine the reaction precisely by an appropriate electroanalytical chemistry technique.⁶ Fig. S8 presents a generation rate of H₂O₂ that was yielded by a two-electron ORR.⁴ Lower H₂O₂ generation rate means that the ORR predominantly proceeds via a four-electron O₂ reduction reaction. The estimated H₂O₂ generation rate was close to 0 % at ca. 0.68 to 0.90 V. At potentials where O₂ reduction current was reached to the diffusion-limited current, H₂O₂ production was recognized, but the H₂O₂ generation rate maintained low values that were below 7% even at 0.10 V. This result shows that the Pt–SWCNT has a favorable electrocatalytic activity for ORR.
