Materials

Silica gel (40 µm) was from SiliCycle. All reagent-grade materials were from Sigma–Aldrich (St. Louis, MO) and were used without further purification, except for 2-hydroxymethylphenylboronic acid and 5-amino-2-hydroxymethylphenylboronic acid, which were from Combi-Blocks (San Diego, CA).

General Experimental

Solvent removal. The phrase “concentrated under reduced pressure” refers to the removal of solvents and other volatile materials using a rotary evaporator at water aspirator pressure (<20 torr) while maintaining the water-bath temperature below 40 °C. Residual solvent was removed from samples at high vacuum (<0.1 torr). The term “high vacuum” refers to vacuum achieved by mechanical belt-drive oil pump.

NMR spectroscopy. $^1$H, $^{13}$C, and $^{11}$B NMR spectra for all compounds were acquired on Bruker Spectrometers in the NMRFAM at the University of Wisconsin–Madison operating at 500 and 125 MHz. The chemical shift data are reported in units of $\delta$ (ppm) relative to residual solvent and to 20% v/v BF$_3$-etherate in CDCl$_3$ as an external standard for $^{11}$B NMR spectroscopy.

Absorption and emission spectroscopy. Fluorescence spectra were measured with a Photon Technology International 810 fluorometer using right-angle detection. Ultraviolet–visible absorption spectra were measured with a Varian Cary 300 Bio diode array spectrophotometer and corrected for background signal with a solvent-filled cuvette. Fluorescence quantum yields in CHCl$_3$ were determined relative to quinine sulfate in 1 N H$_2$SO$_4$, and were corrected for solvent refractive index and absorption differences at the excitation wavelength.

Analyses of deprotection. Deprotection reactions were run with 4-bromo-2,6-dimethylaniline as an internal standard. Samples were taken from the deprotection reaction mixtures at known times and diluted with methanol, and the extent of cleavage was analyzed with an LCMS-2020 single quadrupole liquid chromatograph mass spectrometer from Shimadzu (Kyoto, Japan) using an H$_2$O/MeCN (0.1% v/v formic acid) gradient suitable for baseline separation of starting material and the internal standard.
Evaluation of Other Protecting Groups

Fig. S1  Other potential protecting groups evaluated experimentally.

The above compounds were tested for complexation of 1a by refluxing in ethanol or toluene. (Dean–Stark conditions applied in the case of toluene.) The potential protecting groups were selected because they possess a donor nitrogen ligand that would lead to a charge neutral complex (i.e., a tertiary or pyridine nitrogen).

Discussion. Except for 10, all of the protecting groups above did not form complexes with 1a that were stable to chromatographic and/or extractive purification. Notably, 19, 26 and 28 formed complexes that were stable enough for characterization (see table of contents), but were too fragile for further manipulation. Compounds 28 and 29 have been described to form complexes with borinic acids, but were not effective for benzoxaborole.1 Of particular note is the failure of 20—a 5-membered variant of 10—as a protecting group. Potential protecting groups with oxygen ligands (-OH, -CO2H) would often form protected products that were distinguishable by TLC, but would decompose during subsequent extractive or chromatographic purification. Finally, protecting groups that were able to form 6-membered ring complexes with 1a were formed more readily.
Deprotection Analyses

**Fig. S2.** Kinetic traces for the deprotection of compound 11a. Percent cleavage was determined through comparison of integrations against the internal standard from the LCMS trace and averaged from replicates. Data were fitted to an exponential decay curve with the program Prism 5.0 from GraphPad Software (La Jolla, CA).

**Discussion.** The complex shows modest kinetic stability in the presence of certain anhydrous acids such as BF$_3$(EtO)$_2$ and 4 M HCl in dioxane. The initial cleavage rates for these two acids began at 20% due to contaminating water. The synthesis of 17 and 18 confirms the complexes kinetic stability to anhydrous acid and susceptibility to aqueous acid (see Scheme 3 in the main text). Finally, extent of cleavage was made based on disappearance of 11a because boronic acids have poor detection thresholds under LCMS. The cleaved product was confirmed to be the expected benzoaxaborole as shown in Fig. S32.

**Synthetic Procedures**

**Synthesis of 1c.** 2,5-Bis(hydroxymethyl)phenylboronic acid (0.41 g, 2.5 mmol) was dissolved in DCM (25 mL).
