Experimental

Surface morphology of the membranes

PFSA membranes with various IEC values were boiled in 3 vol\% H\textsubscript{2}O\textsubscript{2} solution and 1 M H\textsubscript{2}SO\textsubscript{4} at 80 \textdegree C for 1 h, respectively. And then, the membranes were boiled in deionized water for 1 h and repeatedly washed in fresh water until pH = 7. The treated membranes were dried in a vacuum oven at 80 \textdegree C for 2 h.

Surface morphology of all PFSA membranes before Fenton test was observed by scanning electron microscopy (SEM). Additionally, for better understanding the changes of the membranes during Fenton test, the morphology of the membranes after being immersed in 30 vol\% H\textsubscript{2}O\textsubscript{2} solution without addition of Fe\textsuperscript{2+} at 80 \textdegree C for 120 h was also examined. The results are depicted in Fig. S1. Clearly, all PFSA membranes before Fenton test show very smooth surfaces. There are also no obvious changes even when the membranes were immersed in H\textsubscript{2}O\textsubscript{2} solution for 120 h. The results indicate that the appearance of bubbles and pinholes on the membrane surfaces after Fenton test are caused by degradation rather than the self-swelling in pure H\textsubscript{2}O\textsubscript{2} solution. Therefore, the
damage degree of the membranes during Fenton test can be used to evaluate their chemical durability.
