Estimation of Metal salts. A stock solution of compound (1) (1.0 × 10^{-3}) and (2) (1.0 × 10^{-3} M) were prepared in CH$_3$CH$_2$OH/H$_2$O (1:1, v/ v). Solutions of 2.0 × 10^{-4} M salts of the respective cation were prepared in distilled water. All experiments were carried out in CH$_3$CH$_2$OH/H$_2$O solution (CH$_3$CH$_2$OH/H$_2$O = 1:1, v/v, 10 μM HEPES buffer, pH = 7.0). In titration experiments, each time 4 × 10^{-5} M solution of (1) and (2) were filled in a quartz optical cell of 1 cm optical path length, and the ion stock solutions were added into the quartz optical cell gradually by using a micropipet. Spectral data were recorded at 1 min after the addition of the ions. In selectivity experiments, the test samples were prepared by placing appropriate amounts of the anions/cations stock into 2 mL of solution of (1) (1.0 × 10^{-3}) and (2) (1.0 × 10^{-3} M).

**Fig. S16** SEM images of complex Cu$^{2+}$–compound (2) (a) 20 µm and (b) 10 µm.
Scanning electron microscopy (SEM) was used to analyze the surface morphology of the microstructure of the resulting compounds (1), (2) and its complexes with Cu$^{2+}$. Platinum was coated on the surface of compound (1) and images at 20 and 2 µm are shown in Fig. S13a and b respectively. The ligand (1) shows a highly porous structure and grass like structure. The ligand (2) illustrated microrods like structure (Fig. S15a and b). We observed considerable change in the ligands morphology when cobalt ion was added to them (i.e. in the complex). The complex of (1) with Cu$^{2+}$ ion, shows the grass covered with large amount spherical particles like surface morphology (Fig. S14a and b), but their size was relatively different. The complex of (2) with Cu$^{2+}$ ion, shows self-assembled microsheets (Fig. S16a and b).
**Molecular modeling: docking study**

Docking calculations were carried out by Docking Server.\(^1\) Gasteiger partial charges were additional to the ligand atoms. Non-polar hydrogen atoms were merged, and rotatable bonds were defined. Necessary hydrogen atoms, Kollman united atom type charges, and solvation parameters were added with the aid of AutoDock tools.\(^2\) Affinity (grid) maps of \(\times\times\) Å grid points and 0.375 Å spacing were generated using the Autogrid program.\(^3\) AutoDock parameter set- and distance-dependent dielectric functions were used in the calculation of the van der Waals and the electrostatic terms, respectively. Docking simulations were performed using the Lamarckian genetic algorithm (LGA) and the Solis & Wets local search method.\(^4\) Initial position, orientation, and torsions of the ligand molecules were set randomly. All rotatable torsions were released during docking. Each docking experiment was derived from 10 different runs that were set to terminate after a maximum of 250000 energy evaluations. The population size was set to 150. During the search, a translational step of 0.2 Å, and quaternion and torsion steps of 5 were applied.

The native structure of 4LRH, 4EKD, 4GIW and 4L9K are taken from the Protein Data Bank. Docking studies were performed with the online docking server, which utilizes the Lamarckian Genetic Algorithm (LGA) implemented therein. For the docking of the drug with 4LRH, 4EKD, 4GIW and 4L9K, the required file for the ligand (corresponding to the three-dimensional structure of the drug compound (1) and (2)) was created through the combined use of the Gaussian 03W and Docking Server. The geometry of compound (1) and (2) are first
optimized at the DFT B3LYP/6-31G level of theory using the Gaussian 03W suite of programs and the resultant geometry was read in the online docking server software in a compatible file format, from which the required file was generated in online docking server.

Fig. S24 HOMO-LUMO energy gap of compound (1) with its Cu$^{2+}$ complex
Fig. S25 HOMO-LUMO energy gap of compound (2) with its $\text{Cu}^{2+}$ complex.
Fig. S26 Molecular electrostatic potential (MEP) surface of compounds (a and b) (1) and (2) with Cu$^{2+}$ (c and d).
**Molecular electrostatic potential (MEP) maps**

To predict reactive sites for electrophilic and nucleophilic attack for the investigated molecule, MEP is calculated (red is negative, blue is positive) at the B3LYP/6–31G and LANL2DZ (d) optimized geometries. Fig. S26a-d show the calculated 3D electrostatic potential contour map of compound (1) and (2) with Cu$^{2+}$. The different values of the electrostatic potential at the surface are represented by different colors. Potential increases in the order red < orange < yellow < green < blue. The color code of these maps is in the range between $-0.0786 \text{ e}^{-2}$ (deepest red) to $0.0370 \text{ e}^{-2}$ (deepest blue) in compound (1) and $-0.0766 \text{ e}^{-2}$ (deepest red) to $0.0561 \text{ e}^{-2}$ (deepest blue) in compound (2), where blue indicates the strongest attraction and red indicates the strongest repulsion. From this result, it is clear that the H atoms indicate the strongest attraction and O atoms indicate the strongest repulsion in compound (1) and (2). Where as the copper atom indicate the strongest attraction and O atom indicate the repultion in compound (1) and (2) with Cu$^{2+}$ complex.

Fig. S28 Mulliken atomic charges of (A) compound (1) and (B) (2).
Charge distribution

The charge distribution of the molecule has been calculated on the basis of Mulliken method using a B3LYP/6-31G level calculation. This calculation depicts the charges of the every atom in the molecule. Distribution of positive and negative charges is the vital to increasing or decreasing of bond length between the atoms. Mulliken atomic charges and the plot have shown in Fig. S28. The Mulliken scheme places the negative charge more or less evenly on C5, C7, C8, C10, C11, N12, N13, C15, C16, C17, C18, C19 atoms and C1, C2, C3, C4, O10, N11, O12, N13, C15, C16, C18, O20, C21 atoms in compound (1) and (2) respectively and splits the positive charge among the all hydrogen atom and some of the C1, C2, C3, C4, C9, C14 atoms in (1) and C5, C6, C7, C8, C9, C14, C17 atoms in (2) Mulliken population analysis compute charges by dividing orbital overlap evenly between the two atoms involved.
