Experimental Procedure

Unless otherwise indicated, all reagents were commercially available and used directly from the supplier without further purification. 1H and 13C NMR were recorded at 20.6 °C using CDCl3 (7.27 ppm) unless otherwise indicated. Chemical shift values are expressed in parts per million (ppm) and J-values in Hertz (Hz). Splitting patterns are indicated at s: singlet, d: doublet, t: triplet, q: quartet, quint: quintet, sex: sextet, sept: septet or combination br s: broad singlet or m: multiplet. FT-IR were recorded using a Perkin Elmer FTIR monitor. GC-MS were recorded on a Varian CP-3800 gas chromatography unit coupled with a 2200 Saturn MS detection unit. Injection occurred at 25 °C and increased at a rate of 10 °C/min until 300 °C was achieved. A reverse phase column (30 M X 25 µM X 0.25 mM) was used, and mass spectrometry data was analysed with NIST 05 molecular recognition software.

Table 1. Percent conversion for a ratio of \(n\)-butanol to acetic acid of 1:1.5 as a function of choice of acid catalyst, for the VFD (17.5 mm internal diameter NMR tube) operating at \(\theta 45^\circ\), and 5250 rpm, for a flow rate of 0.50 mL/min.

Fabrication of a high contact angle surface 20 mm VFD tube

A 17.5 mm internal diameter NMR tube was filled with fresh piranha solution and left for one hour. Following this, the tube was rinsed with Milli-Q water (10 x 25 mL) and then placed in the oven at 150 °C for 16 hrs. The tube was removed from the oven and 75 % volume was filled with toluene, following this trichlorododecyl silane (2 mL) was added and then toluene was added until the NMR tube was full, and after standing for 24 hrs, the solution was removed and the tube then rinsed with toluene (2 x 10 mL), followed by water (2 x 10 mL).
