**General experimental**

All reagents which are commercially available were used without further purification. Solvents for monomer synthesis were also commercially obtained: dichloromethane (DCM) was anhydrous (≥ 99.8%) grade and tetrahydrofuran (THF) was anhydrous (≥ 99.9%) grade from Sigma-Aldrich®. For polymerisation, THF was distilled from sodium and benzophenone. THF was degassed 10 minutes before using on polymerisation. Thin-layer chromatography (TLC) was carried out on MERCK TLC silica gel 60 F254 and flash column chromatography was performed using MERCK silica gel 60 (0.040~0.063 mm). \(^1\)H NMR and \(^13\)C NMR were recorded by Varian/Oxford As-500 (500 MHz for \(^1\)H and 125 MHz for \(^13\)C) and Bruker (300 MHz for \(^1\)H and 75 MHz for \(^13\)C) spectrometers. UV–vis spectra were measured by Jasco Inc. UV/vis-Spectrometer V-550. Gel permeation chromatography (GPC) for polymer molecular weight analysis was carried out with Waters system (1515 pump, 2414 refractive index detector) and Shodex GPC LF-804 column eluted with THF (GPC grade, Honeywell Burdick & Jackson®). Samples in 0.001-0.003 wt% THF were filtered with a 0.45-μm PTFE filter before injection. Flow rate was 1.0 mL/min and temperature of column was maintained at 35 °C. High resolution mass spectroscopy (HRMS) analyses were performed by the National Center for Inter-University Research Facility.

**Experimental procedure for catalyst**

**Third-generation Grubbs catalyst (1)**

Second-generation Grubbs catalyst (51.8 mg, 0.0610 mmol) and 3-chloropyridine (1 mL) were mixed in 20-ml sized vial for 5 minutes. Cold \textit{n}-pentane was poured to the vial. After storage in freezer a few hours, the solid was filtered and washed by pentane. The green product (39.1 mg, 0.0491 mmol, 80.5%) was dried \textit{in vacuo} and stored in desiccator.

**General polymerisation procedure (poly(M1) - poly(M4))**

Monomer (0.100 mmol) was weighed in a 5-ml sized screw-cap vial with septum and purged with argon. Distilled and degassed solvent (0.4 mL) was added to the vial. The solution of initiator (0.1 mL) was added at once under vigorous stirring. After confirming the monomer conversion by TLC, the reaction was quenched by excess ethyl vinyl ether. The concentrated reaction mixture was precipitated by methanol, and the obtained dark-purple solid was dried \textit{in vacuo}.
Polymerisation of M3 using other catalyst

![Chemical structure of 1-b]

We tested the polymerisation of M3 to confirm the reactivity of 1-b\(^4\), which was also known Ru catalyst for promoting the cyclopolymerisation of 1,6-hepadiyne derivatives. Catalyst efficiency was checked beforehand by the polymerisation of diethyl dipropargylmalonate over 90\% of conversion. The polymerisation condition varied with the solvent (THF/DCM) and temperature (rt – 45 °C). The [M]/[I] was 50, reaction time was over 16 hr, and concentration was 0.4 M. Monomer conversion was confirmed by crude \(^\text{1}^\text{H}\) NMR, recording roughly 30\%. Yield could not be calculated because there was no precipitated polymer but only the suspension of the polymer mixed with remaining monomer. This suspension was analyzed by SEC after dry, resulting in small part of polymer (M\(_\text{n}\)~ 6-7000) and a large peak of unreacted monomer.

Diblock copolymerisation procedure of poly[(M5)-b-(M4)]

2,2-Di(prop-2-ynyl)propane-1,3-diyI dipropionate (M5)\(^5\) (0.01 g, 0.038 mmol) was weighed in a 5-ml sized screw-cap vial with septum and purged with argon. Distilled and degassed THF (0.05 mL) was added to the vial. The vial was placed in a cold bath. The solution of initiator (0.0012 g, 0.0015 mmol) in THF (0.05 mL) was added at once under vigorous stirring. After confirming the monomer conversion by TLC (15 minutes), M4 (0.03 g, 0.076 mmol) in THF (0.2 mL) was added rapidly at room temperature. After 24 hr, the reaction mixture was quenched by excess ethyl vinyl ether. The concentrated reaction mixture was precipitated by methanol, and obtained red solid was dried in vacuo.
