General Methods

Infrared (IR) spectra were obtained using a Jasco 260 Plus Fourier transform infrared spectrometer. Proton and carbon magnetic resonance spectra ($^1$H NMR and $^{13}$C NMR) were recorded on a Bruker model DRX 400, DRX 500, or a Bruker AVANCE III 600 CryoProbe ($^1$H NMR at 400 MHz, 500 MHz or 600 MHz and $^{13}$C NMR at 101, 126, or 151 MHz) spectrometer with solvent resonance as the internal standard ($^1$H NMR: CDCl$_3$ at 7.26 ppm, CD$_3$OD at 3.35 ppm; $^{13}$C NMR: CDCl$_3$ at 77.0 ppm, CD$_3$OD at 49.2 ppm). $^1$H NMR data are reported as follows: chemical shift, multiplicity (s = singlet, d = doublet, t = triplet, dd = doublet of doublets, ddd = doublet of doublet of doublets, sext = sextet, m = multiplet, br. s. = broad singlet), coupling constants (Hz), and integration. Mass spectra were obtained using a positive ion mode flow injection ESI (electrospray ionization) on a Bruker Daltonics, Inc., Billerica, MA, USA, BioToF Mass Spectrometer. Thin layer chromatography (TLC) was performed on SiliaPlate 250 µm thick silica gel plates provided by Silicycle. Visualization was accomplished with short wave UV light (254 nm), aqueous basic potassium permanganate solution, or ethanolic acidic $p$-anisaldehyde solution followed by heating. Flash chromatography was performed using SiliaFlash P60 silica gel (40-63 µm) purchased from Silicycle. Tetrahydrofuran, diethyl ether, and dichloromethane were dried by passage through a column of neutral alumina under nitrogen prior to use. All other reagents were obtained from commercial sources and used without further purification unless otherwise noted. Compressed oxygen was purchased from Airgas, National Welders Supply Company.
Compound Preparation

Styrene, β-methylstyrene, p-methoxystyrene, o-bromostyrene were purchased from commercial sources, purified by distillation, deoxygenated via multiple freeze-pump-thaw cycles, and stored at -35 °C under an inert atmosphere prior to use. Norbornene was purified by sublimation and stored under an inert atmosphere.

Para-trifluoromethylstyrene\(^1,2\) and 2-vinylnapthalene\(^1,3\) were prepared according to standard procedures. All physical and spectral data were in accordance with literature data. N-Phenylhydroxylamine was synthesized according to literature procedures.\(^4,5\) Physical and spectral data were in accordance with literature data.\(^6\)

General Procedure for Preparation of \(N\)-Phenyl Hydroxamic Acids

Unsaturated hydroxamic acids 1, 3, 7, 9, 11, and 15 were synthesized as previously described using either Method A or B as described below.\(^5,7\)

Note: All \(N\)-aryl hydroxamic acids should be purified promptly upon formation and stored neat at -40 °C.

Method A

To a 0 °C solution of carboxylic acid (1 mmol) in DCM (1.4 mL) and DMF (10 drops) was added oxalyl chloride (2 mmol) dropwise under an argon atmosphere. The solution was stirred at 0 °C for 15 min., warmed to room temperature and stirred for 2 h. The resultant yellow solution was then evaporated almost to dryness under reduced pressure before sodium bicarbonate (2 mmol) was added and the mixture redissolved in \(\text{H}_2\text{O}/\text{Et}_2\text{O} (1 \text{ mL}/2 \text{ mL})\). The solution was then cooled to 0 °C, \(N\)-phenylhydroxylamine (1 mmol) added, and the reaction stirred at 0 °C for 3.5 h. The layers were separated, the aqueous layer was acidified with 1 M \(\text{NaHSO}_4\) and extracted with \(\text{Et}_2\text{O} (x \ 3)\). The combined organic layers were then washed with brine, dried (\(\text{MgSO}_4\)), and concentrated to give crude product that was purified by flash chromatography to yield the corresponding \(N\)-phenyl hydroxamic acid.

Method B

\[

\]

To a solution of aldehyde (1 mmol), nitrosobenzene (1 mmol), and triazolium salt (0.10 mmol) in CH\(_2\)Cl\(_2\) (4.5 mL) under Ar was added DBU (0.10 mmol). The solution color rapidly changed from green-blue to amber over 15 min. stirring at rt. Upon TLC visualization of consumption of aldehyde, solvent was removed under reduced pressure and the resultant oil was purified via flash chromatography to yield the corresponding N-phenyl hydroxamic acid. Note: this procedure was not effective for the synthesis of \(\alpha\)-disubstituted N-aryl hydroxamic acids.

Synthesis of 18: To a 0 ºC solution of methyl chloroformate (1.6 mL, 20.2 mmol, 1.1 equiv.) in Et\(_2\)O (40 mL) and a saturated aqueous solution of sodium bicarbonate (20 mL) was added N-phenylhydroxylamine (2.0 g, 18.3 mmol, 1.0 mmol). The solution was stirred at 0 ºC for 3 h then warmed to room temperature. The layers were separated, the aqueous layer was acidified with 1 M NaHSO\(_4\) and extracted with Et\(_2\)O (x 3). The combined organic layers were then washed with brine, dried (MgSO\(_4\)), and concentrated to give an oil that was purified by flash chromatography to give methyl N-hydroxy(phenyl)carbamate 18 (2.92 g, 17.5 mmol, 95% yield) as an off-white solid. All spectra were in accordance with literature data.\(^9\)

General Ketoxyamination Conditions

Caution! Aerobic reactions in organic solvents may produce potentially explosive peroxides. Alkylhydroperoxides are produced using the following conditions. While no problems were encountered in this work, alkylhydroperoxides are prone to rapid exothermic decomposition and appropriate care should be taken in their handling.

For Intramolecular Ketoxygenations

A new 1-dram vial containing a magnetic stir bar was charged with unsaturated hydroxamic acid (1.0 equiv.) and dissolved in nBuOAc to make a 0.1M solution. The vial was fitted with a PTFE-lined screw cap and O₂ was bubbled through the solution for 10 min. The reaction was allowed to stir under 1 atm O₂ at 60 °C. Upon disappearance of the hydroxamic acid substrate, as indicated by TLC analysis, the reaction mixture was cooled to rt and 4-(dimethylamino)pyridine (DMAP, 10 mol %) and acetic anhydride (Ac₂O, 1 equiv) were added under Ar. Upon completion of the elimination, as indicated by TLC analysis, the crude reaction mixture was diluted with EtOAc (10 mL), washed with H₂O (2 x 5 mL) then brine, dried (MgSO₄), and concentrated. The resulting cyclic hydroxamate was purified by flash chromatography using the specified solvent system.

The strong COSY between $H_a$ and the multiplet at 2.6 ppm identifies $H_d$. The nOe between $H_c$ and $H_d$ indicates that the ring junction is cis.
The strong COSY between $H_a$ and the multiplet at 3.2 ppm identifies $H_b$. The nOe between $H_a$ and $H_b$ indicates that the ring junction is cis. Additionally, $H_a$ appears as a doublet at 4.3 ppm, $J=9.4$Hz.
By analogy to our previously reported dioxygenation of norbornene and in conjunction with the strong COSY observed between H_{a} and H_{bh1} and the absence of an nOe between H_{a} and H_{bh2}, we assign the stereochemistry shown to the left.
