General Information

General Methods: Experiments involving moisture- and/or air-sensitive compounds were conducted under an inert atmosphere in an argon-filled drybox or by standard Schlenk techniques. Non-aqueous reagents were transferred by hypodermic syringe under an atmosphere of argon. When necessary, solvents were degassed by purging with argon for at least 15 min just prior to use. Heating was accomplished by silicon oil bath using a temperature controller. Organic solutions were concentrated under reduced pressure using a Büchi rotatory evaporator, unless otherwise noted. Reactions were magnetically stirred and monitored by thin-layer chromatography (TLC) carried out on 0.25 mm E. Merck silica gel plates (60–F254) using UV light as a visualizing agent and a KMnO₄ solution or a ceric ammonium molybdate (CAM) solution, and heat as developing agent. Flash chromatography was carried out with ZEOCHEM ZEOprep 60 (particle size 40–63 µm) according to the procedure of Still and coworkers.[1] Yields refer to chromatographically and spectroscopically (¹H NMR) homogeneous (>95%) materials, unless otherwise stated. ¹H and ¹³C NMR spectra were recorded with a Bruker AVANCE III 300 (300 MHz and 75.5 MHz, respectively) spectrometer. Chemical shifts of the ¹H NMR (CDCl₃: 7.26 ppm) and ¹³C NMR (CDCl₃: 77.0 ppm, C₆D₆: 168.02 ppm) spectra were referenced to residual solvent peaks or tetramethylsilane (0.00 ppm) as an internal standard. ¹H NMR spectra are reported as follows: chemical shift, multiplicity (br = broad, s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet), coupling constant (Hz) and integration. When necessary, the multiplicities of the carbons were determined by DEPT (Distortionless Enhancement by Polarization Transfer) experiments. Samples for NOESY experiments were deoxygenated by applying freeze-pump-thaw (3-4 cycles) to a tick-wall NMR tube equipped with a J-Young valve. HPLC analysis was performed on a Young Lin instrument YL9100 HPLC system using chiral stationary phase columns (Daicel Chiralcel OD-H 250 × 4.6 mm ID and Daicel Chiralpak AD-H 250 × 4.6 mm ID). Optical rotations were obtained using a Rudolph Autopol III digital polarimeter and optical rotation data are reported as follows: [α]D²² (concentration c = g/100 mL, solvent). Melting points were measured using an electrothermal IA9100 digital melting point apparatus and are uncorrected. High-resolution mass spectra (HRMS) were obtained from the Korea Basic Science Institute, Daegu Center, Daegu, Korea on a JEOL.

JMS700 high-resolution mass spectrometer using the technique of EI (electron impact ionization) or FAB (fast atom bombardment).

Materials: Unless otherwise noted, all reagents were purchased at the highest commercial quality from common commercial suppliers (Sigma Aldrich, TCI, Acros and Strem) and used without further purification. \([\text{Ir(cod)Cl}_2]\) was purchased from Strem and stored in an argon-filled drybox. Phosphoramidite ligand \(L_1\) and \(L_2\) were prepared according to the literature procedures and stored in an argon-filled drybox.\(^{[2]}\) \((E)\)-Ethyl 2-hydroxy-4-phenylbut-3-enoate \((1'')\) was prepared through the \(\text{NaBH}_4\) reduction of \((E)\)-ethyl 2-oxo-4-phenylbut-3-enoate\(^{[3]}\) using the literature procedure.\(^{[4]}\) The Stewart-Grubbs catalyst was purchased from Sigma Aldrich and stored in a desiccator. Tetrahydrofuran (THF), 1,2-dimethoxyethane and 1,4-dioxane were freshly distilled from sodium/benzophene ketyl under an atmosphere of argon. Nitromethane was refluxed over \(\text{CaH}_2\), fractionally distilled under an atmosphere of argon and stored over 4 Å molecular sieves. Acetonitrile and dichloromethane were freshly distilled from \(\text{CaH}_2\) under an atmosphere of argon. Diethyl ether was freshly distilled from \(\text{LiAlH}_4\) under an atmosphere of argon. Allylamine was dried with KOH overnight and fractionally distilled from \(\text{CaCl}_2\) just prior to use under an atmosphere of argon. Benzylamine (Na), diallylamine (KOH), morpholine (Na) and propylamine (Zn dust) were dried with KOH overnight, fractionally distilled from an appropriate drying agent under an atmosphere of argon and stored over 3 Å molecular sieves. Aniline and \(N\)-methylaniline were dried with KOH overnight, fractionally distilled from KOH under reduced pressure and stored over 3 Å molecular sieves. A solution of lithium hexamethyldisilazide (LiHMDS) was freshly prepared by dissolving lithium hexamethyldisilazide (Sigma Aldrich) in anhydrous THF (1.0 M solution) under an inert atmosphere at room temperature just prior to use.

General Procedure for Olefin Cross-Metathesis Reaction: A 100-mL Schlenk-type flask equipped with a magnetic stirring bar and a reflux condenser was charged with the Stewart-Grubbs catalyst (57.2 mg, 0.100 mmol, 2.00 mol%), evacuated and back-filled with argon (3 cycles). A solution of allylic alcohol (5.00 mmol, 1.00 equiv) in dry degassed CH\textsubscript{2}Cl\textsubscript{2} (25 mL in total) was added to the flask containing the catalyst via double-ended needle. The resultant dark green mixture was treated with an appropriate acrylate (25.0 mmol, 5.00 equiv) and then heated under reflux in a pre-heated oil bath (bath temperature = 53 °C) for 24 h. After which the mixture was cooled to room temperature and concentrated to afford a residue, which was purified by flash column chromatography (hexanes/EtOAc) on silica gel to afford the desired (E)-\(\alpha\),\(\beta\)-unsaturated \(\gamma\)-hydroxy ester as a single trans-diastereomer. When ethyl acrylate or methyl acrylate was employed, the following procedure was adapted to remove an excess amount of the acrylate. Upon completion of the olefin CM reaction, the reaction mixture was cooled to room temperature and the reaction vessel was equipped with a fractional distillation apparatus. Under an atmosphere of argon, the mixture was heated gradually in an oil bath up to 105 °C. During the course of the heating a mixture consisting of acrylates and dichloromethane was distilled off and collected in a pear-shaped flask. Heating was continued until the distillation ceased. The system was then allowed to cool to room temperature and the distillation apparatus was carefully disassembled. The flask containing the crude reaction mixture along with a small amount of acrylates was connected to a high-vacuum line equipped with a cold trap and the mixture was stirred vigorously for 5 min. The flask was then disconnected from the line. All the apparatuses used were washed thoroughly with methanol and the wastes were collected and treated with an aqueous solution of KOH to destroy the acrylates.
Preparation of (E)-Ethyl 4-Hydroxy-4-phenylbut-2-enoate (1a'):\(^5\) Prepared using 1-phenylprop-2-en-1-ol\(^1\)\(^6\) (671 mg, 5.00 mmol, 1.00 equiv) and ethyl acrylate (Caution! Acrid odor) (2.5 g, 25.0 mmol, 5.00 equiv) in dry degassed CH\(_2\)Cl\(_2\) (25 mL). (E)-ethyl 4-hydroxy-4-phenylbut-2-enoate (842 mg, 82%) was isolated (hexanes/EtOAc = 4:1→3.5:1) as a yellow oil. Alternatively, it can be prepared from (E)-ethyl 4-oxobut-2-enoate as follows. To a cold solution of (E)-ethyl 4-oxobut-2-enoate (1.28 g, 10.0 mmol, 1.00 equiv) in anhydrous THF (24 mL) at -78°C was added dropwise phenylmagnesium bromide (1.0 M solution in THF, 12.0 mL, 12.0 mmol, 1.20 equiv) and the mixture was stirred at the same temperature for an additional 10 min. The reaction was quenched with a saturated solution of ammonium chloride (20 mL) and the mixture was extracted with EtOAc (3 × 15 mL). The combined extract was washed with water and brine (a saturated aqueous solution of NaCl), dried over anhydrous Na\(_2\)SO\(_4\), filtered, and concentrated. The crude mixture thus obtained was purified by flash column chromatography (hexanes/EtOAc = 3.8:1→3.5:1) on silica gel to afford the desired carbinol (1.33 g, 65%) as a yellow oil. \(^1\)H NMR (CDCl\(_3\), 300 MHz) \(\delta\) 7.38–7.26 (m, 5H), 7.02 (dd, \(J = 15.6, 4.8\) Hz, 1H), 6.12 (dd, \(J = 15.6, 1.5\) Hz, 1H), 5.31 (d, \(J = 3.6\) Hz, 1H), 4.16 (q, \(J = 7.2\) Hz, 2H), 2.78 (br s, 1H), 1.26 (t, \(J = 7.2\) Hz, 3H); \(^13\)C NMR (CDCl\(_3\), 75.5 MHz) \(\delta\) 166.4, 148.4, 140.9, 128.8, 128.4, 126.6, 120.3, 73.5, 60.5, 14.2; HRMS (EI) exact mass calculated for [M]\(^+\) (C\(_{12}\)H\(_{14}\)O\(_3\)) requires \(m/z\) 206.0943, found \(m/z\) 206.0944.

**General Procedure for the Formation of \textit{tert}-Butoxy Carbonates:** To a cold solution of carbinol (1.00 equiv) in anhydrous THF (2.50 mL/1.00 mmol) at −78 °C (acetone/dry ice bath) was added dropwise LiHMDS (1.0 M solution in THF, 1.20 equiv) via double-ended needle and the resultant mixture was kept stirring at the same temperature for 60 min. To this mixture was added a solution of \textit{di-\textit{tert}}-butyl dicarbonate (1.20 equiv) in THF (2.00 mL/1.00 mmol). The system was allowed to slowly warm to 0 °C over several hours. The reaction was then quenched with brine and the mixture was extracted with EtOAc (3 × 15 mL). The crude mixture thus obtained was purified by flash column chromatography (hexanes/EtOAc) on silica gel column to afford the desired carbonate.

General Procedure for the Formation of Oxazolidin-2-ones (3): In an argon-filled drybox, a 5-mL screw-capped vial reactor was charged with [Ir(cod)Cl]$_2$ (6.7 mg, 0.010 mmol, 2.0 mol%) and rac-L1 (10.8 mg, 0.020 mmol, 4.0 mol%) and a small magnetic stir bar was added into the vial. The vial was sealed with a cap containing a PTFE septum and removed from the box. Dry degassed THF (0.30 mL) was added under an atmosphere of argon and the resultant reddish mixture was stirred for 10 min at room temperature. Distilled propylamine (0.20 mL) was then added and the resultant mixture was heated at 50 °C in a pre-heated oil bath with stirring for 20 min. After which the mixture was cooled to room temperature and all volatiles were removed in vacuo. To the vial reactor containing the activated catalyst was added a solution of substrate 1 (0.500 mmol, 1.00 equiv) in dry degassed nitromethane (0.50 mL) via double-ended needle. The resultant yellow mixture was stirred at room temperature for 10 min before the addition of distilled allylamine (0.600 mmol, 1.20 equiv) via microsyringe. After stirring for 13 h, the mixture was diluted with EtOAc, filtered through a small pad of silica gel, and concentrated. The crude mixture thus obtained was analyzed by $^1$H NMR and then purified by flash column chromatography (hexanes/EtOAc = 4:1→3:1→2:1) on silica gel to afford the oxazolidin-2-one 3 as an inseparable mixture of trans- and cis-diastereomers. The structure of 3a was confirmed by extensive 1D and 2D NMR analyses such as $^1$H, $^{13}$C, DEPT-135, DEPT-90, COSY, HSQC and NOESY. The relative configuration of the major trans-isomers were assigned on the basis of the vicinal coupling constants between the C-4 and C-5 protons, whose values are consistent with the ones reported for similar oxazolidin-2-ones,[19] and further confirmed by NOESY experiments. For other oxazolidin-2-ones, $^1$H, $^{13}$C, COSY and NOESY spectrums are provided.

Preparation of trans-Ethyl 2-(3-Allyl-2-oxo-5-phenyloxazolidin-4-yl)acetate (3a):

Prepared using (E)-ethyl 4-(tert-butoxycarbonyloxy)-4-phenylbut-2-enoate (1b, 153 mg, 0.500 mmol, 1.00 equiv) and distilled allylamine (34.3 mg, 0.600 mmol, 1.20 equiv) in dry degassed nitromethane (0.50 mL), ethyl 2-(3-allyl-2-oxo-5-phenyloxazolidin-4-yl)acetate (120 mg, 83%) was isolated (hexanes/EtOAc = 2:1) as an inseparable 10:1 mixture of trans- and cis-diastereomers (a pale yellow oil).
