**Experimental Section**

**Scheme S1.** Schematic illustration of the selective growth process of Ag/Ag₃PO₄ core-shell hetero-nanowires.

1. **Synthesis of rectangular silver nanowires**

The silver nanowires were firstly prepared by a modified polyol process. In a typical synthesis, 1, 2-Propylene glycol (1, 2 PG, 10mL) that contained poly (vinyl pyrrolidone) (PVP, \( M_w \approx 50000 \), 150 mM as calculated in terms of the repeating unit) was placed in a 25-mL vial, capped, and heated with stirring in an oil bath at 160 °C for 1 h. 1 mL NaCl solution (1 mM in 1, 2 PG) was then quickly added. After 5 min, AgNO₃ (0.15 M solution in 1, 2 PG) was added with drop by drop to the stirring solution. The vial was then capped and heated at 160 °C for 40 min. After injection of the AgNO₃ solution, the color of reaction mixture changed from milkiness to light yellow, and silvery white. The reaction solution was cooled to room temperature. Finally, the as-prepared Ag nanowire samples were washed with distilled water for several times to remove...
excess polyols and PVP via centrifugation, and dispersed in the aqueous solution containing PVP with a concentration of 200 mM.

2. Synthesis of Ag/Ag₃PO₄ hetero-nanowire

As shown in the above Scheme S1, the as-prepared Ag nanowires were added into silver-ammino ([Ag(NH₃)₂]⁺) complex aqueous solution (0.2 M) with stirring for 20 min. Then, Na₂HPO₄ aqueous solution (0.15 M) was added, and Ag nanowire/Ag₃PO₄ cube heterostructure have been synthesized. The above samples were diluted with water and stirred strongly for 20 min. Finally, the obtained Ag/Ag₃PO₄ hetero-nanowire samples were dried at room temperature.

3. Photocatalytic Reactions

In all catalytic activity of experiments, the samples (0.2 g) were put into a solution of RhB dyes (100 ml, 8 mg/L), which was then irradiated with a 300W Xe arc lamp equipped with an ultraviolet cutoff filter to provide visible light with λ ≥ 420 nm. The degradation of organic dyes was monitored by UV/Vis spectroscopy (UV-2550, Shimadzu). Before the spectroscopy measurement, these photocatalysts were removed from the photocatalytic reaction systems by a dialyzer.

4. Characterizations

SEM images were taken using a field-emission scanning electron microscope (JSM-6701F, JEOL) operated at an accelerating voltage of 5 kV. An energy-dispersive (ED) detector was equipped with this field-emission scanning electron microscope and operated at an accelerating voltage of 15 kV. The X-ray diffraction spectra (XRD) measurements were performed on a Philips X’pert MPD instrument using Cu Kα radiation (50 kv). The XRD patterns were recorded from 10° to 90° with a scanning rate of 0.067°/ s. UV/Vis absorption spectra were taken at room temperature on a UV-2550 (Shimadzu) spectrometer. The photoluminescence (PL) spectra of the photocatalysts were measured on the Hitachi F-7000 Fluorescence spectrophotometer with an excitation wavelength of 440 nm.
Additional Figures and Discussions

Fig. S1. (A-D) SEM images of Ag/Ag₃PO₄ core-shell hetero-nanowires with different magnifications.
Results and discussions:

According to Kubelka-Munk Function, the relation between absorption coefficient and band gap energy can be described by the equation

\[(\alpha h\nu)^{1/2} = A(h\nu - E_g)\]

in which \(\alpha\), \(\nu\), \(A\) and \(E_g\) are absorption coefficient, light frequency, proportionality constant and band gap, respectively. Plot \((\alpha h\nu)^{1/2}\) vs \(h\nu\) and the bandgap could be evaluated by extrapolating the straight line to the \(h\nu\) axis intercept. As shown in the above figure, the band-gap of Ag/Ag\(_3\)PO\(_4\) nanowires is 2.40 eV, indicating that the Ag/Ag\(_3\)PO\(_4\) core-shell structure possess same band gap with pure Ag\(_3\)PO\(_4\) particles. Accordingly, the conduction band potential and valence band potential energy for the composite is 0.45 and 2.85 eV.\(^{[1,2]}\)

Results and discussions:

To further investigate the enhanced photocatalytic activity over Ag/Ag₃PO₄ nanowires, their photoluminescence (PL) spectra have been measured to explain the migration, transfer, and recombination processes of the photoinduced electron–hole pairs in this core-shell heterostructure. Fig. S7 shows the PL spectra of Ag/Ag₃PO₄ core-shell hetero-nanowire, Ag₃PO₄ cubes, Ag₃PO₄ particles. Obviously, the pure Ag₃PO₄ cubes and particles have a strong and wide peak in the range of 500-575 nm and a small peak around 660 nm respectively in the PL spectrum. However, in the case of the Ag/Ag₃PO₄ core-shell hetero-nanowires, both the strong peak and small peak have been greatly decreased, which clearly indicate that the photoinduced electron–hole pair can migrate easily between Ag nanowire and Ag₃PO₄ nanoshell and the recombination of electrons and holes is greatly hindered. This demonstration clearly reveals that the formation of Ag/Ag₃PO₄ core-shell hetero-nanowire can serve as an alternate approach to reduce the recombination rate of the photoinduced electron–hole pair and improve the corresponding photocatalytic activity.
Results and discussion:

Except for the photocatalytic performances, the photoelectric conversion properties over Ag/Ag₃PO₄ core-shell nanowires, Ag₃PO₄ cubes, and spherical particles deposited on Tin-doped indium oxide (ITO) glass have been detailedly investigated. As shown in Fig. S8, it can be found that the Ag/Ag₃PO₄ core-shell nanowires exhibit higher photoelectric conversion efficiency than Ag₃PO₄ cubes and commonly spherical Ag₃PO₄ particles, clearly indicating that the formation of Ag/Ag₃PO₄ core-shell nanowires could effectively promote the separation of photogenerated electron-hole pairs and decreasing their recombination ratio. These results clearly indicating that structure-controlled synthesis of metal/Ag₃PO₄ hetero-nanomaterials is also very feasible strategy for enhancing their photoelectric performances.
