ICP analysis was measured with 50 mL solution of palladium ions from 20 mg of solid sample. Through calcining, dissolving, and filtrating processes, the sample were detected by inductively coupled plasma optical emission spectroscopy (ICP-OES).

\[
\text{Pd loading (wt%)} = \frac{3.929 \text{ mg/L } \times 0.05 \text{ L}}{20 \text{ mg}} = 0.98\%
\]
**Additional experiments:**

To explore the influence of Pd(0) nanoparticle size on the catalytic results, a series of additional experiments were carried out as follows.

**Preparation of GO-NEt₂-2N supported Pd(0) nanoparticles.**

Pd(0) nanoparticles were deposited on modified GO (GO-NEt₂-2N) by employing two different reductants: hydrazine hydrate and hydrogen. GO-NEt₂-2N was firstly prepared through the procedure as described. Typically, 8.8 mg of PdCl₂ powder (0.05 mmol) and GO-NEt₂-2N (50 mg) were dispersed in 50 mL water. The mixture was stirred for 1 h at room temperature. Pd(0) nanoparticles reduced by hydrazine hydrate (Pd-MGO-N₂H₄) was synthesized by adding 156 mg (80 wt%, 2.5 mmol, 50 equiv. of Pd) of hydrazine hydrate, and the mixture was stirred at 90 °C for 1 h. Pd(0) nanoparticles reduced by hydrogen (Pd-MGO-H₂) was obtained by bubbling hydrogen for 1 h with a flow of 40 mL min⁻¹. After the reaction, the resulting mixtures were filtered and washed with water multi times until no palladium ions were detected in the filtrate, followed by freeze-drying.

**Characterization and catalytic tests.**

The samples were characterized by TEM and ICP. As shown in Fig. S5 below, images reveal that Pd-MGO-N₂H₄ and Pd-MGO-H₂ exhibit nanoparticle size of 25 ± 5 nm and 3 ± 1 nm, respectively. The Pd contents of Pd-MGO-N₂H₄ and Pd-MGO-H₂ amount to 4.98% and 3.72%, respectively.

The efficiency tests of the catalysts towards Tsuji–Trost allylation were conducted under the same conditions as described. The results are summarized in Table S2. As a control, the catalytic result of commercial Pd/C catalyst is also listed in the table.

Discussion and conclusion.

As seen in Table 1, all of the samples exhibit good efficiency towards the Tsuji–Trost allylation. Pd-MGO-H$_2$ shows a comparable activity with the commercial Pd/C catalyst, while Pd-MGO-N$_2$H$_4$ gives a lower conversion compared with Pd-MGO-H$_2$ and commercial Pd/C catalyst. Therefore, Pd(0) is also an effective species towards the Tsuji–Trost allylation, and smaller nanoparticle size of Pd(0) tends to give a higher catalytic activity.
