**Photophysical Methods**

**Linear absorption and emission spectra measurements**

Linear absorption spectra were recorded on a Shimadzu 3150 PC spectrophotometer with freshly prepared sample solutions in various solvents (1×10⁻⁵ M). The same sample solutions were also used for the measurement of one-photon-induced fluorescence emission spectra and life-time by utilizing a Jobin-Yvon FluoroMax-4 spectrometer equipped with TCSPC accessories (FluoroHub-B + NanoLED from Jobin-Yvon). The aforementioned fluorospectrometer equipped with an integrated sphere (Labsphere from Jobin-Yvon; diameter = 100mm) was also employed to measure the absolute fluorescence quantum yield of each model compound in solution phase (1×10⁻⁵ M) at room temperature;¹ Coumarin 153 (Φ_F = 0.38±5% at λ_exc = 423 nm) was used as the standard for the calibration of the integrated sphere and the instrument.²,³

**Two-photon-excited fluorescence (2PEF) measurements**

Two-photon-excited fluorescence spectra of the studied model fluorophores in solution phase (concentration: 1×10⁻⁴ M) were measured according to the protocol established by Xu and Webb using Fluorescein (0.1N NaOH solution) as the standard.⁴ The experimental setup is illustrated in Figure S1. In brief, the excitation light source was a mode-locked Ti:Sapphire laser (Tsunami pumped with a Millennia 10W, Spectra-Physics) which delivers ~80fs pulses with the repetition rate of 80MHz and the beam diameter of 2mm. The intensity level of the excitation beam was carefully controlled by a λ/2 wave plate in order to avoid the saturation of absorption and photodegradation. To minimize the effects of re-absorption, the excitation beam was focused as close as possible to the wall of the quartz cell (10mm×10mm cuvette) and the 2PEF emissions were collected and induced by a fiber bundle into a CCD imaging spectrometer (USB-4000, Ocean Optics) for the spectra recording. This optical system was also utilized for the characterization of the quadratic dependence of the 2PA-induced up-conversion emission intensity on the pumping intensity for every data point.

Effective optical-power limiting property studies

Effective optical-power limiting performance of compounds 1-4 in solution phase (0.02M in THF, light path-length = 1 cm) was probed at ~800nm using nanosecond laser pulses as the working tool. As shown in Figure S2, a nanosecond tunable laser system (an integrated OPO and Q-switched Nd:YAG laser: NT 342/3 from Ekspla) were employed as the excitation source to provide ~6 ns laser pulses with repetition rate of 10 Hz for this study. The laser beam was slightly focused onto the center of the sample solution in order to obtain a nearly uniform laser beam radius within the whole cell path-length. The local intensity within the sample solution was tuned by adjusting the incident laser power level with the aid of a ND filter set. In all cases, the energy of transmitted laser beam from the sample cell was detected by an optical power (energy) meter with a large detection area of ~25 mm in diameter.
